EASTER HOLIDAYS—Advertisements and Communications for our issue of April 4th, 1931: see Notice on page 2 (Advts.).

BILIARY STASIS AND GALL-BLADDER DISEASE

It is stated that ten per cent. of our entire adult population suffer from gall-stones. As gall-stones, presumably, always follow infective inflammations, cholecystitis must be even more common.

The relative frequency with which the gall-bladder is infected, on the one hand, by the bile received from a liver whose detoxicating capacity has been lowered, and, on the other hand, directly by the blood supplied through the cystic artery, is not determined; but, in either case, biliary stasis is a prominent etiological factor in actual gall-bladder disease. The importance of promoting more active intestinal peristalsis and a hastened biliary flow is therefore obvious.

Through the force of osmosis, the flow of bile into the intestine may, as the duodenal tube has revealed, be stimulated by suitable saline draughts, of which Eno's "Fruit Salt" is perhaps the most agreeable and most generally useful. It is suggested that many early cases of cholecystitis—apt to be cursorily dismissed with the vague diagnosis "dyspepsia"—might be arrested by such simple means as increased exercise and regular morning draughts of Eno's "Fruit Salt."

Eno is chemically pure, and free from all trace of the nauseous mineral sulphates—Glauber and Epsom. It contains no sugar or artificial flavouring.

"Urgent Abdominal Diagnostics."

The Proprietors of ENO'S "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "Urgent Abdominal Diagnostics" summarises the salient facts which need to be ever at the front of the mind when faced with an abdominal emergency. The diseased conditions dealt with include those which most often call for immediate surgical attention. It is bound in black morocco limp to conform to the style of the previous publications in this series.

Measuring Progress by the Therapeutic Yardstick

ANCIENT medicine set great store by "specifics." Paracelsus had his "Specificum Purgans." Cophon relied on mirobolanum or rhubarb in relieving constipation. Suppositories of honey and oxgall had their day in the fifteenth century.

Medicine has since made notable advances toward rationalism. In this day of therapeutic progress Agarol Brand Compound holds the foremost place. An exceptionally fine emulsion of mineral oil and agar-agar with phenolphthalein, it is not merely a laxative, but a remedial measure in the efficient treatment of constipation.

By introducing unabsorbable moisture, Agarol Brand Compound keeps the intestinal contents soft and makes their passage easy and painless. By *gentle stimulation* of peristalsis, it makes the result certain and aids in re-establishing normal bowel function.

One tablespoonful at bedtime —is the adult dose

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

A New Book

MOORHEAD'S TRAUMATOTHERAPY

Just Issued

This is a book on the *immediate treatment of the injured*—the immediate, the thorough, the complete treatment. Dr. Moorhead considers every accident case an emergency case, demanding treatment *at once!* The necessity for this has been driven home to him through long years in the field of traumatic therapy—a field in which he is one of the pioneers.

This is *an entirely new book*, giving the immediate steps to be taken in every possible kind of accident, the application of drugs, solutions, dressings, splints, apparatus of all kinds, physiotherapy. It tells you how first to help relieve the patient; then how to treat the injury, how to restore speedily the greatest possible function. There is no other book like this in the English language.

Octavo of 574 pages, with 602 illustrations. By JOHN J. MOORHEAD, B.Sc., M.D., F.A.C.S. (D.S.M.), Professor of Surgery and Director, Department of Traumatic Surgery, New York Postgraduate Medical School and Hospital. Cloth, 32s. 6d. net.

DEVELOPMENTAL ANATOMY

By LESLIE BRAINERD AREY, Robert Laughlin Rea Professor of Anatomy, Northwestern University Medical School. Large octavo of 560 pages, with 1,037 illustrations on 532 figures. New, 2nd Edition. Cloth, 27s. 6d. net.

"Professor Arey has published a text-book which includes more post-natal development than most other manuals of embryology. The outline presented of the more important developmental changes manifested after birth is a very valuable addition. . . . Professor Arey is to be congratulated on the production of a text-book of embryology which may be highly recommended and is likely to be used very widely."—BRITISH MEDICAL JOURNAL.

MEDICAL BIOMETRY & STATISTICS

By RAYMOND PEARL, Professor of Biology, School of Hygiene, Johns Hopkins University. Octavo of 459 pages, illustrated. Second, Revised, Edition. Cloth, 25s. net.

"An interesting and useful book which will appeal to many others besides those for whom it is primarily intended."
—JOURNAL OF THE INSTITUTE OF ACTUARIES.

TEXT-BOOK OF MEDICINE

Edited by RUSSELL L. CECIL, M.D., Assistant Professor of Clinical Medicine, Cornell Medical School. Octavo of 1,592 pages, illustrated. Second Edition. Reset. Cloth, 40s. net.

"This book maintains a very high level throughout its pages. . . . Great care has been taken with the dovetailing together of the various contributions into a compact whole, and the book is a worthy production of the modern American school of medicine."—THE LANCET.

TEXT-BOOK OF HISTOLOGY

By ALEXANDER A. MAXIMOW, late Professor of Anatomy, University of Chicago. Completed and edited by WILLIAM BLOOM, Assistant Professor of Anatomy, University of Chicago. Large octavo of 833 pages, with 604 illustrations, some in colours. Cloth, 40s. net.

"The book is one which can be recommended with confidence as a general work of reference for the more advanced student of this branch of study."—BRITISH MEDICAL JOURNAL.

ORTHOPEDIC SURGERY

By WILLIS C. CAMPBELL, M.D., F.A.C.S., Professor of Orthopedic Surgery, University of Tennessee. Octavo of 705 pages, with 507 illustrations. Cloth, 37s. 6d. net.

"The book can be recommended with confidence to the general surgeon, as well as to the specialist who is called upon to treat such affections. It is nicely illustrated, and many radiograms are reproduced. The general production of the volume—binding, print, etc.—is excellent, and we foretell for it every success."—IRISH JOURNAL OF MEDICAL SCIENCE.

MAYO CLINIC: PAPERS OF 1929

By W. J. & C. H. MAYO and their ASSOCIATES at the Mayo Clinic and the Mayo Foundation, University of Minnesota. Octavo of 1,197 pages, with 279 illustrations. Cloth, 60s. net.

"There could be no better mirror of the progress of surgical science than the Mayo Clinic volumes. Each department of the Clinic keeps itself informed of what is being done elsewhere, and every new suggestion is put to the test on a scale and with a thoroughness which cannot be matched in many clinics."—THE LANCET.

W. B. SAUNDERS COMPANY Ltd., 9, Henrietta St., London, W.C.2

CASSELL AND COMPANY, LTD.

RADIUM THERAPY: PRINCIPLES AND PRACTICE

By **G. E. BIRKETT**, *M.C.*, B.A.Cantab., M.R.C.S.Eng.,

Honorary Radiologist, Manchester and District Radium Institute and Christie Hospital for Cancer.

"The book is well and simply written, there is a good index, and the illustrations are excellent."
—BRITISH MEDICAL JOURNAL.

"Presents concisely and attractively the position that has been reached in this branch of therapeutics."—LANCET.

HENRY KIMPTON'S NEW PUBLICATIONS

NEW WORK. *THIS DAY.*

THE

PATHOLOGY OF INTERNAL DISEASES

By WILLIAM BOYD, M.D., M.R.C.P.(Edin.), Dipl. Psych., F.R.S.C.,

Prof. of Pathology in the Univ. of Manitoba; Pathologist to the Winnipeg General Hosp., Winnipeg, Canada.

Royal octavo, 888 pages, with 293 illustrations. Cloth. Price 45s. net.

This is a truly useful pathology—unique in scope, form and method. It shows the inter-relations of anatomy and histology, of pathological physiology and clinical medicine, thus filling a gap that the textbooks have always left vacant. It is an illustrated textbook of internal medicine based on the mechanism of disease. Its references are those that the practitioner will find most useful. Its illustrations are profuse and mostly original, and its discussion of each subject leads straight to the relation of symptoms to lesions. The book is brilliantly written. It reveals the hidden processes of disease without a knowledge of which the physician is all too likely to grope in the dark. Every page is interesting, stimulating, and, above all, helpful. Here is a pathology you will use.

NEW (FOURTH) EDITION. *JUST READY.*

MODERN METHODS OF TREATMENT

By LOGAN CLENDENING, M.D.

Fourth Edition, Revised and Enlarged. Large octavo, 819 pages, with 95 illus. Cloth. Price 42s. net.

"The book is one which deserves its success."—*British Medical Journal.*

ABDOMINO-PELVIC DIAGNOSIS IN WOMEN

By ARTHUR JOHN WALSCHEID, M.D.

Large octavo, 1,000 pages, with 397 illustrations and a coloured plate. Cloth. Price 52s. 6d. net.

¶ An authoritative work beautifully illustrated.

NEW WORK. *READY NEXT WEEK.*

THE

DIAGNOSIS and TREATMENT of BRAIN TUMORS

By ERNEST SACHS, M.D.

Large octavo, 396 pages, with 224 illustrations, including 10 in colours. Cloth. Price 42s. net.

¶ A special feature of this work is the large number of original drawings made under the personal supervision of the author by trained medical artists. 217 of these are half-tone engravings and line drawings. There are six beautiful coloured plates, all of which add greatly to the value of the text.

NEW (SECOND) EDITION. *JUST READY.*

AN INTRODUCTION TO

CLINICAL PERIMETRY

By H. M. TRAQUAIR, M.D., F.R.C.S.Edin.,

Ophthalmic Surgeon, Royal Infirmary, Edinburgh; Ophthalmic Surgeon, Chalmers Hospital, Edinburgh; Oculist to the Edinburgh Poorhouse; Lecturer on Diseases of the Eye, Edinburgh University.

Second Edition, Revised and Enlarged. Demy quarto. 289 pages, with 179 illustrations and 3 coloured plates. Cloth. Price 30s. net. Postage 9d.; abroad 1s. 6d.

Extracts from reviews of first edition:

"A book which should find its way into every ophthalmic surgeon's library."—*British Journal of Ophthalmology.*
"We can heartily recommend this work."—*Edinburgh Medical Journal.*
"The work should prove invaluable alike to the ophthalmologist and to the neurologist."—*Lancet.*
"Maintains a high standard of excellence."—*British Medical Journal.*

RECENTLY PUBLISHED. FIFTH EDITION. Fully Revised and Enlarged. Crown 8vo. 1,048 pp. 21s. net; postage 9d.

SYNOPSIS OF

MEDICINE

By H. LETHEBY TIDY, M.A., M.D., B.Ch.Oxon., F.R.C.P.Lond.,

Physician, St. Thomas's Hospital; Consulting Physician, Royal Northern Hospital.

"An admirable *index medicus*. . . . The scope is far wider than in the majority of books Throughout, 'treatment' meets with ample consideration . . . this fact alone will enhance its value enormously for the busy practitioner."—BRIT. MED. JOURN.

"We can say without hesitation that the book is far ahead of any medical synopsis it has been our lot to encounter."—LANCET.

"We have nothing but admiration for this book, and cannot commend it too highly."—MEDICAL PRESS AND CIRCULAR.

NINTH EDITION. Fully Revised. Crown 8vo. 684 pp. With 165 Illustrations, some of which are coloured. 17s. 6d. net; postage 9d.

SYNOPSIS OF

SURGERY

By ERNEST W. HEY GROVES, M.S., M.D., B.Sc.Lond., F.R.C.S.Eng.,

Professor of Surgery, Univ. of Bristol; Surgeon, Bristol General Hospital; Member of the Court of Examiners, Royal College of Surgeons, England; Examiner in Surgery, Universities of London, Liverpool, Leeds, Manchester and Sheffield, and Nat. Univ. of Ireland.

"Complete in its range of subjects . . . among the best of its kind; the author is to be congratulated on its readableness, its lucidity and its fullness—notable qualities."—BRIT. MED. JOURN.

"This synopsis of surgery has had a wide sale, which has necessitated the issue of frequent editions, and it deserves thoroughly all the success it has attained."—LANCET.

Why not get your Frigidaire now before it's *REALLY HOT?*

YOU, of all men, can appreciate the health benefits of refrigeration. You've probably already made up your mind to have a Frigidaire, sometime. But why put it off? Think how pleasant to come down to dinner these hot evenings after a hard day's work and know there was a really cold drink awaiting you, a crisp, cool, refreshing salad, iced butter, and no worry for your wife about the meat or the children's milk "going off." Such a difference! And if you send in the coupon below, though you are committed to nothing, you'll be able to see how little such luxury would cost you.

The Quickube Ice Tray, enabling single cubes, or many, or all, to be extracted at once, simply by a light pressure of the finger. No melting them out under the water tap. Your cocktail ice is ready at a moment's notice.

The Cold Control, by which the freezing of ice cubes or any other frozen delicacy can be accelerated at will.

The automatic feature of Frigidaire is invaluable. It cuts out the human element with its forgetfulness and consequent waste. Frigidaire maintains a dry cold that is *always* under 50°—the only safe temperature for food.

Practical flat top, makes a useful shelf.

The Hydrator—a *moist* cold compartment, for fresh vegetables, sandwiches, etc., etc. Even wilted vegetables will regain their crispness here in a few hours.

Ease of installation. A Frigidaire only needs connection with your electric supply. No plumbing is necessary.

The new Frigidaire is quiet—you can't hear it start, stop or run.

Showrooms at 141, New Bond Street, London, W.1, and in all principal towns.

FRIGIDAIRE LIMITED (*Incorporated in Canada*)
Dept. BG-283, Edgware Road,
The Hyde, Hendon, N.W.9.

Please give me by return, without any obligation on my part,
(a) Price of Frigidaire cabinet suitable to my particular needs as below:
or
(b) Amount to be paid down to cover initial deposit, installation and carriage charges.

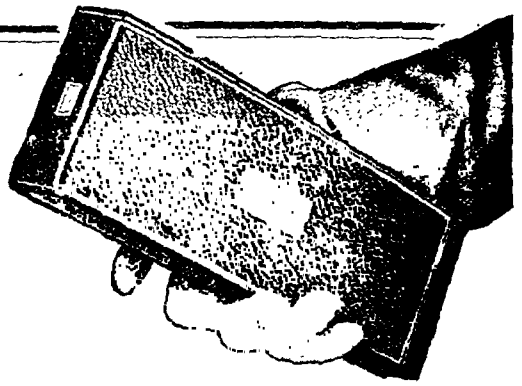
THE NEW KOMPAK MODEL



In the selection of blood-pressure apparatus the physician is influenced by only one major consideration.

Is it accurate—and will it remain accurate?

Scientific accuracy — the dominating feature of the Baumanometer — is attested by more than one hundred thousand physicians the world over.

Other distinguishing features of simplicity, durability, and portability are immediately apparent.

Among the Lifetime Baumanometer Models available is the New KOMPAK Model, the smallest, the lightest, and the handiest mercurial instrument.

Like all Lifetime Baumanometers, it too is a MASTER instrument, individually calibrated, scientifically accurate and guaranteed to remain so. It also carries our exclusive guarantee against glass breakage.

Your surgical instrument dealer will gladly demonstrate it or send one to you.

Note its distinguishing specifications.

Lifetime Baumanometer
STANDARD FOR BLOODPRESSURE

Calibration: 260 mm.
Size: 1⅝" x 3⅞" x 11⅝".
Weight: 30 oz.
Inflation System Self-Contained.
Duralumin case with baked enamel edges.
Genuine Morocco grain leather.
Entire manometer unit chromium plated.
Individual nameplate cast in cover.
Table of clinical averages embossed in case.
Lifetime Guarantee against glass breakage.
Perpetual Guarantee for accuracy.

Obtainable from leading Surgical Equipment Houses, or

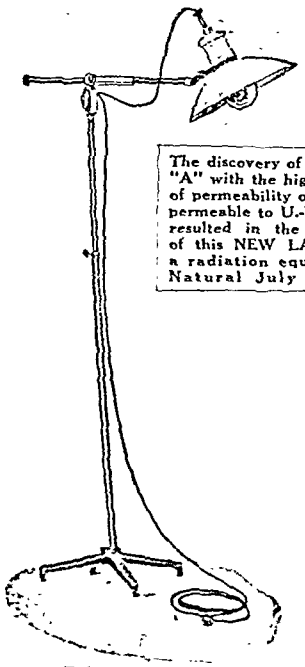
GRSA

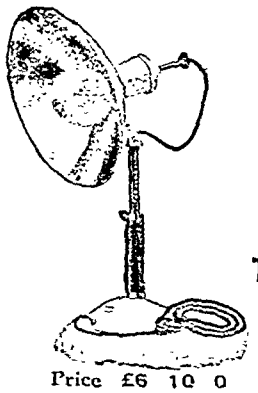
NERON VITALUX

The Sunlight Generator

HEAT, LIGHT, ULTRA-VIOLET



The discovery of U.-V. Glass "A" with the highest degree of permeability of all glasses permeable to U.-V. Rays has resulted in the production of this NEW LAMP giving a radiation equivalent to Natural July Sunlight.



Price £8 10 0

Price £6 10 0
Complete with bulb.

An indication as to some of its uses:

Rachitis prophylaxis, tubercular cervical glands, surgical and cutaneous tuberculosis, neuralgia, rheumatism (neuritis, myalgia), catarrhal diseases (colds), inflammation of the lungs (pleurisy), treatment of wounds, abscesses, furuncles, fungoid diseases of the skin, barber's rash, frontal sinus catarrh.

Extract from letter recently received from a doctor:
"The lamp is giving me thorough satisfaction, being a great improvement on the carbon arc lamp I was using, owing to the absence of fumes and greater ease of working, as well as giving a more satisfactory spectrum."

Neron Vitalux Lamps are being installed in various hospitals, etc.

MICKLEFIELD IRRADIATED MILK

TREATING THE COW

By this Process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED.
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil.

A ten weeks' test recently conducted at the Infants' School, Rickmansworth, under the supervision of the Medical Officer of Health, gave the following results:—

(1) 18 children (controls) had their usual ordinary milk.
(2) 29 " 1/3-pint of Grade A (T.T.) milk five days a week.
(3) 30 " " Micklefield " " "

(1) Average increase in height '605-in. (2) Average increase in weight 9·72 ozs. more than (1).
(2) " " " '610-in. (3) " " " 10·9 ozs. more than (1).
(3) " " " '744-in.

Full particulars appeared in an article in the LANCET, January 18, 1930, p. 127, et seq., a reprint of which will be sent post free on request.

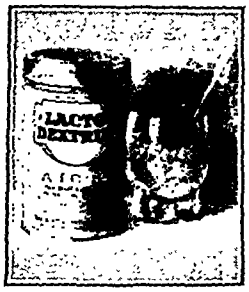
The milk is delivered every week-day in London; elsewhere by arrangement.

Write to J. O. HICKMAN, MICKLEFIELD GREEN, RICKMANSWORTH.

Of special service in FISSURE or HAEMORRHOIDS

"PSYLLIUM seeds when immersed in water yield a mucilaginous substance which is able to take up relatively large quantities of water to form a gelatinous mass. They become in this way a useful lubricant, while the emollient character of the mass renders it of special service in fissure or haemorrhoids."—*Lancet*, Jan. 10th; 1931.

Another preparation of importance as a laxative agent is Lacto-Dextrin—a palatable combination of lactose and dextrin for changing the intestinal flora.



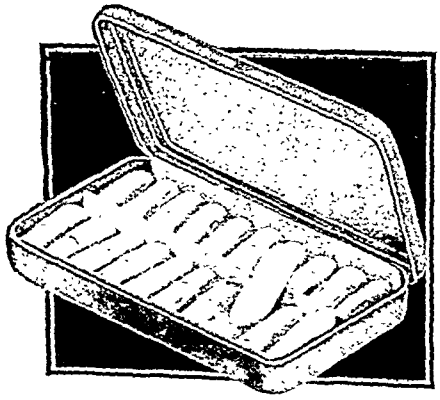
Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, 41, Great Tower Street, London, E.C.3, Solé Distributing Agents for the United Kingdom and Irish Free State.

PSYLLA *(Psyllium Seed)*

LACTO-DEXTRIN

Products of the BATTLE CREEK FOOD CO., Mich., U.S.A.

A *New* chemo-therapeutical preparation *for the treatment of influenza, septic diseases and toxemias*



Used in America for treating Influenza for the past two or three years with great success. The physician's sample illustrated here will be sent to you free on request.

Indications.
Influenza Colds, Pyelitis, Puerperal Sepsis, Surgical Sepsis, Bronchial Asthma, Obstetric Morbidity, Cystitis, etc.

DISULPHAMIN is a mixture of Sulpho-salicyl formol sodium nucleinate and Dimethylamino-antipyrin combined with camphor. The antitoxic action is based on the assumption that Disulphamin transforms the toxic colloid to a crystalloid, thereby facilitating its dialysis through the walls of the blood vessels, and accelerating its elimination by the kidneys.

While phenol is bactericidal in a 1/100 dilution, Disulphamin is bactericidal in a dilution of 1/10,000 to 1/50,000.

In a series of tests made in the treatment of Influenza with Disulphamin, it was found that the course of the disease was materially shortened, and very seldom did Broncho-pneumonia or other complications supervene. Although the etiology of influenza has not yet been clearly determined, it appears that Disulphamin exerts a polyvalent action.

The clinical results thus far obtained are so encouraging that physicians have ample justification for employing Disulphamin in *Febrile* Toxemias arising from Sepsis.

Samples and literature, including charts of actual tests and important hospital findings, will be sent free on request to Messrs. COATES & COOPER, 41, Great Tower Street, London, E.C.3.

THE BIO-CHEMICAL LABORATORIES
LOCARNO, SWITZERLAND

For Replenishing Depleted Reserves

Radiostoleum supplies a valuable revitalising factor in the treatment of debility, lethargy and lack of tone—conditions which inevitably arise during the spring, particularly after influenza and other prevailing illnesses of the winter.

Radiostoleum is also a valuable anti-infective agent; not only does it act prophylactically in building up resistance against infectious diseases, particularly those of the respiratory organs and of the middle ear, but it is being used with considerable success also in the treatment of various acute infections.

By virtue of its content of Vitamins A and D it possesses the power to promote healthy growth in the young, and to control calcium and phosphorus metabolism in old and young alike.

Radiostoleum administration is beneficial, therefore, in building up resistance during pregnancy, in lactation, in infancy, at puberty and the menopause, and in old age.

It is prescribed also with success in dental caries; in fact, in their fight against disease, physicians are finding in Radiostoleum a valuable adjunct to their armamentarium.

After Milk—WHAT?

"Infants even as early as the third month will digest appreciable quantities of starch."*

This statement reflects the growing tendency among medical practitioners to-day to introduce a starchy food into infant diet at a much earlier stage than was hitherto considered necessary or advisable.

Four noteworthy advantages of early starch feeding given recently by a leading pediatrist are:

Slower carbohydrate digestion, allowing thorough hydrolysis lasting over a period from one feed to another.

Less tendency to fermentative diarrhoea.

Metabolisation of fat.

Retarded curd formation.

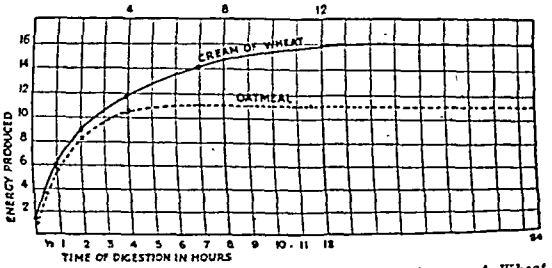
Research Institute proves "Cream of Wheat" to be more digestible than oatmeal and productive of 50% more energy

"Cream of Wheat," long successful as a food for infants, *has now been proved by a leading British biochemical* institute to possess definite advantages over oatmeal.

Reference to recent text-books and monographs shows that many of the leading pediatrists of the day have placed this wheat-cereal on their diet sheets for infants.

It is made from the finest wheat and has a starch content of 72 per cent. Containing none of the husk, it causes no irritation in the intestinal tract, and can be confidently given not only to infants, but to adults during the post-operation period and convalescence.

A sample of "Cream of Wheat" and a full account of the tests described here will gladly be sent on receipt of your professional card. Dept. W2, Fassett & Johnson, 86, Clerkenwell Road, London, E.C.1.



Replica of graph showing Diastatic Digestion of "Cream of Wheat" compared with that of oatmeal. After 4 hours the digestion of oatmeal was practically at a standstill, while that of "Cream of Wheat" continued at a scarcely diminished rate for a further 4 hours. Further, the sugar yield from "Cream of Wheat" was 50 per cent. greater than oatmeal—making it productive of 1½ times as much energy.

* "*Infant Feeding*," by Clifford G. Grulee, A.M., M.D., LL.D. (J. & A. Churchill).

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

DINNEFORD & Co. LTD.

HORLICK'S MALTED MILK

HORLICK'S MALTED MILK in the diet of the expectant mother is not only of general use, but has also proved of special value for the prevention and relief of morning sickness.

Morning sickness is not an inevitable accompaniment of pregnancy. Even in cases where there is some degree of acidosis due to the drain on the carbohydrate stores of the mother by the growing foetus, or to the patient refusing food because she feels sick, thereby making her condition worse, simple measures frequently suffice to bring relief; in a majority of cases a glass of HORLICK'S taken half an hour before rising—better still, at bedtime and before rising—will prevent any feeling of nausea and discomfort; its delicate aroma and palatability overcome a distaste for food, and its easily digested carbohydrate, by making good the depleted glycogen stores and establishing a reserve, prevents acidosis.

IN ALL DISORDERS ASSOCIATED WITH PYREXIA

BY APPOINTMENT

These essences supply stimulus without strain to the digestive system . . .

In illnesses when the patient is unable to assimilate solid food—and in convalescence when recovery is hampered by anorexia—Brand's Essences of Beef or Chicken provide stimulus while conserving the patient's energy.

For scientific tests have proved that these essences are assimilated by the digestive organs forty minutes quicker than the time taken for ordinary food—and without the formation of residue. Their action is suave and non-irritating.

For these reasons 99 out of every 100 doctors recently interviewed are recommending Brand's Essences of Beef or Chicken. They find them indispensable in the treatment of specific fevers, in cases of intestinal disturbances, before and after operations, and particularly now in the post-influenzal state when the system must be prepared to digest a solid diet.

Brand's Essences of Beef or Chicken are hygienically prepared under scientific control by an exclusive process. They consist of the pure essence of the finest freshly killed English meats without added colouring matter or preservatives.

Clear, appetizing jelly, they are easy to swallow and delicious to taste. Samples will be gladly sent on receipt of a professional card. Dept. F.29, Brand & Co., Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

Successful Treatment of Hyperchlorhydria and Associated Conditions

"Alocol" (Colloidal Hydroxide of Aluminium) has proved remarkably successful in the treatment of hyperchlorhydria, gastric ulcer, fermentative dyspepsias with gastro-intestinal flatulence, acid eructation and other symptoms common to gastric disease.

The advantages of "Alocol" are that it actually removes from the system the causative acid radicle (Cl) instead of merely neutralising it, and so permitting reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

Furthermore, "Alocol" neither hinders proteolysis nor causes destruction of any food element or factor. "Alocol" has a distinct healing and sedative effect; it promptly allays irritation by absorbing acid and other irritants.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists, 184, Queen's Gate, London, S.W.7.

Cod-Liver Oil Cream

This ethical preparation is particularly acceptable to children. It may be prescribed with confidence that good results will be obtained.

Children take it readily, even where the usual difficulty has been experienced in inducing them to take other forms of Cod-Liver Oil. They rapidly respond to its nutritive and strengthening influence.

The Cream contains 50% of recently refined Cod-Liver Oil of high vitamin content. The fresh eggs used in the making enhance the value of the preparation as a nutrient. The Emulsion is perfect (vide *The Lancet*, Jan. 4th, 1930), rendering the assimilation easy, even in cases where digestion is weak.

The fact that it is freshly prepared every week ensures freedom from loss of vitamin efficiency of the oil, due to storage or exposure to sunlight.

The preparation is endorsed by many members of the Medical Profession.

4/-, 7/-, and 10/-, post free.

Supplied by return of post to ensure freshness.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I have treated with 'Staniform' a very bad scald of chest in a child, who had boiling water spilt over her. It healed completely in fourteen days without a scar."

"I have tried 'Staniform' in the Out-patients' Department and both Nursing Staff and myself were amazed at results obtained. Long-standing, non-healing skin wounds healed after few applications."

"This is to certify that 'Staniform' has been used with great success in the Emma-Klinick (Utrecht, Holland), in cases of bed-sores, in burns of heat and X-rays."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

OF FRESH GRAPES

in a specially rich form.

JUVIGOR

Henri de Bahèzre
Négociant

Maison fondée
en 1808

Made in Nuits-Saint-Georges, in the heart of Burgundy, famous for its wonderful grapes.

Simple but convincing reasons why Juvigor can be recommended to patients.

A glass of Juvigor contains the vital elements of a large bunch of grapes.

Juvigor is absolutely free from preservative, colouring matter, flavouring, or chemicals of any kind.

In making Juvigor only fresh ripe Burgundy grapes are used. These are lightly crushed in order that only the free juice immediately under the skins is extracted. Only this free juice is used because it contains a very much higher percentage of the most valuable constituents of grape juice; it requires between 11 and 12 pounds of grapes to make one large bottle of Juvigor.

The grape juice is pasteurised without destruction of the vitamins and retains in full all its tonic and nourishing elements.

Juvigor is recommended when the vitality is low, in chronic and debilitating diseases such as tuberculosis, after acute diseases like pneumonia and influenza, especially where there is loss of appetite or the stomach is sensitive. In fact, wherever an increase of vitality is desired.

Note:—Generally speaking it is advisable for patients at first to take Juvigor with an equal quantity of water, or soda water, gradually decreasing the amount of water added.

Sold at 3/- and 1/9 per bottle.

Sole Agents: KIA-ORA LTD., BLACKFRIARS, LONDON, S.E.1

(Aesculapius)

COLLOZIN

for the treatment of

ACNE, ECZEMA, URTICARIA, PRURITUS

and similar skin diseases.

Zinc lotions of the ordinary type have several important defects. They leave a granular deposit on the skin after use and soil the clothing. As the therapeutic action is a surface one only, the full value of the remedy is not obtained.

Collozin is a Colloidal Zinc Hydroxide, and is free from these manifest disadvantages. It is a smooth, non-toxic, protective lotion, having mild astringent and antiseptic properties which assist tissue granulation. By reason of its colloidal nature, its action is gentle, consistent, and prolonged; it gives an intimate and invisible distribution of the zinc hydroxide over the skin.

Collozin is also recommended as a protective application to the face against exposure to wind and sun, also after shaving.

Issued in bottles—4-oz., 8-oz., and 16-oz.

Prepared at
EVANS' BIOLOGICAL INSTITUTE, Higher Runcorn, Cheshire.

A Liver Preparation your Patients will enjoy

'Byno' Hepol

Registered.

Trade Mark

For Pernicious Anæmia and Sprue

'Byno' Hepol is a solution of Liver Extract 'A. & H.' in 'Bynin' Liquid Malt.

Supplied in 4 oz. and 10 oz. bottles

The presence of the malt extract assists the digestion and assimilation of the liver which renders its continued use less prone to produce nausea.

Three tablespoonfuls of 'Byno' Hepol are equivalent to eight ounces of fresh mammalian liver, the amount usually ordered to be taken daily in the treatment of pernicious anæmia.

The "Allenburys"

ORANGE JUICE

DOUBLE STRENGTH. SWEETENED.

Supplies a potent source of the anti-scorbutic Vitamin C in a form convenient for infant feeding and other purposes.

It is equivalent to *double strength* fresh orange juice and retains its full activity for a long period.

Employed with advantage in all cases in which fresh orange juice is used.

May be taken by children and adults in the form of a delightful drink by diluting with about ten times its volume of plain or aerated water or milk. Contains no alcohol or chemical preservative.

Further particulars and clinical sample will be sent post free on application.

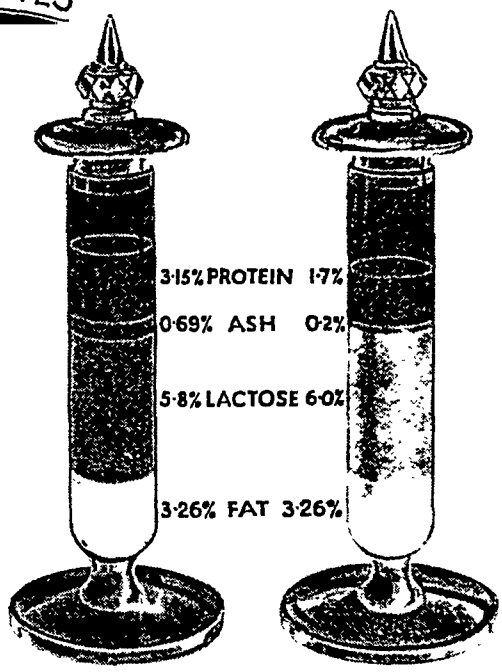
BETTER MILK FOR BABIES

FACTS ABOUT
LACTOGEN



LACTOGEN—diluted by weight with 6½ parts of water.

LACTOGEN MATERNAL MILK

BREAST MILK—Average composition taken from "Principles of Human Physiology"—Starling.

Correct Balance

Lactogen is not merely a dried milk powder, but milk, scientifically modified to provide the physiological balance required by the human infant. The addition of carbohydrate to the cream-enriched fresh milk corrects the natural deficiency and reduces the excess of protein.

The normal constituents of maternal milk are thus furnished in correct proportion. Lactogen is prepared to this unvarying composition:—

Fat	24.5 per cent.
Protein	23.7 „ „
Carbohydrate	43.6 „ „
Mineral Salts	5.2 „ „
Moisture	3.0 „ „
Caloric Value	143 calories per oz.

A Medicinal tablespoonful of Lactogen weighs 0.2 ozs. and furnishes 28.6 calories. To ensure correct and uniform feeds, a hygienic aluminium measure of this equivalent is provided with each tin of the food.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

MAP SHOWING THE DISTRIBUTION OF THE TEUTONIC PEOPLES AT THE CLOSE OF THE FOURTH CENTURY.—The migrating Teutonic tribes came in contact with the Roman Empire which, despite its decaying condition, was still a civilised and highly organised state. This association developed the nationalising instinct in the Teutons. The map shows their distribution just before they began to enter the new territories. The East Goths, or Ostrogoths, stretching from the Dniester to the Don, were soon to found a Teutonic kingdom in Italy. The Visigoths under Alaric, strong in the Balkan Peninsula, presently set up a kingdom in Spain and S.W. Gaul. The Burgundians continued their S.W. course on their way to rule in the Rhone valley. The Vandals, already across the Oder, founded in N. Africa a kingdom reaching from the Atlantic to Tripoli. The Jutes, Angles and Saxons in the N.W. took to the sea, and, after a period of devastation and conquest, became the pioneers of a vigorous civilisation in Britain. In the dearth of exact documents it is possible to give only approximate dates for the founding of these kingdoms; they range generally over the fifth and sixth centuries.

RHEUMATOID and OSTEO-ARTHRITIS

Amidst the recognised difficulties in treatment of advanced cases of Rheumatoid and Osteo-Arthritis it is not generally realized that many patients have been restored to active life after being bedridden, suffering great pain for years, by Hoefftcke's Ambulatory Extension Treatment.

Many cases have been described by eminent medical men, some results of which are shown below.

FIG. 1.—December, 1921.

Case of Mrs. H., aet. 35.

FIG. 1.—Shows the knee-joint fixed in a position of partial flexion; patella ankylosed.

FIG. 2. — Shows after an interval of 9 years the improvement which resulted from 3 years' extension treatment—the complete restoration of the tibio-femoral joint which permits of free and painless flexion and extension.

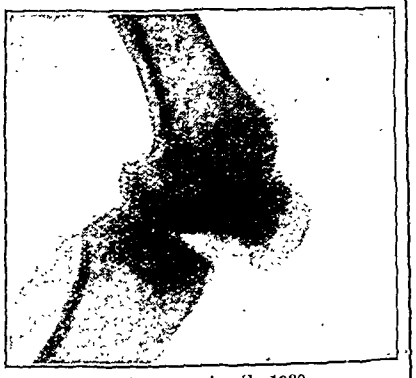

FIG. 2.—April, 1930.

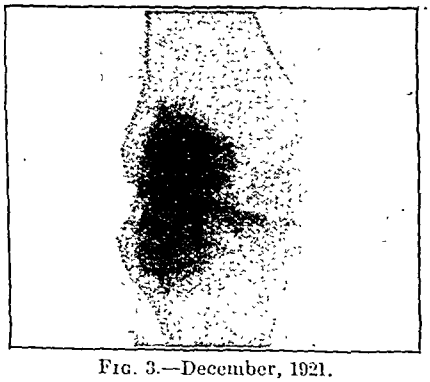

FIG. 3.—December, 1921.

FIG. 3.—Shows the irregularity of the outline of the articular surfaces as seen from before backwards. The interval between the bones is practically obliterated.

FIG. 4.—Shows the joint in an antero-posterior plane. Note the restoration of the outlines of the articular surfaces and the formation of a practically normal interval between the bones.

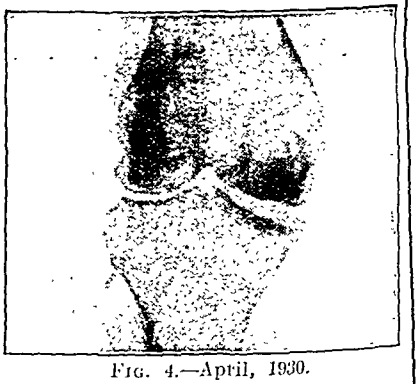

FIG. 4.—April, 1930.

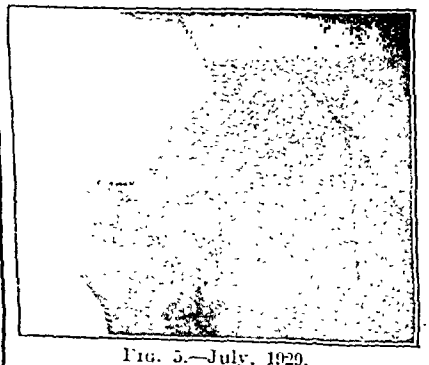

FIG. 5.—July, 1929.

Case of Mr. S., aet. 68.

FIG. 5.—Shows the hip-joint practically ankylosed in the adducted position. Patient hardly able to walk with great pain.

FIG. 6. — Shows spike absorbed; cavity filled in; head of femur covered with new cartilage, resulting in free abduction with full painless movement in the joint.

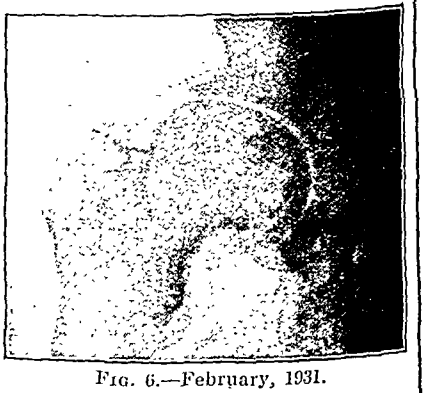

FIG. 6.—February, 1931.

Particulars and illustrations of this treatment will be forwarded on application, and original radiograms of these and other cases can be shown

Observations on DIVERTICULA OF THE COLON AND THEIR SEQUELAE

BY

J. P. LOCKHART-MUMMERY, F.R.C.S.
SENIOR SURGEON, ST. MARK'S HOSPITAL

AND

H. GRAHAM HODGSON, C.V.O., M.B., D.M.R.E.
RADIOLOGIST, KING'S COLLEGE HOSPITAL, LONDON

(With Special Plate)

The formation of diverticula in the wall of the colon and the consequences which may result therefrom have within recent years become of increasing importance in the surgery of that organ. Diverticula are the commonest pathological lesions seen in the large bowel, and they are responsible for the majority of cases of disease of the colon brought to the surgeon and to the radiologist. There is probably no abnormality or disease of the alimentary tract in which radiology has been of more service, both in arriving at a correct diagnosis and in watching the progress of the disease. Uncomplicated cases of diverticula of the colon show no external signs, and the condition cannot be recognized without the aid of *x* rays. Our clinical and radiological experiences will, we hope, prove of value in estimating the probable or possible results in cases of this description.

ETIOLOGY

Normally the mucous membrane of the colon is supported by the circular and longitudinal muscle coats which exist in a continuous sheath between it and the peritoneal covering, and which afford a sufficiently firm support, preventing any tendency to herniation of the mucosa. After about the age of 45 there appears to be a tendency in certain individuals for this muscle sheath to lose its tone; as a result of this, bulging of the mucous membrane tends to occur at the weakest points, these being between the circular muscle fibres, and especially where blood vessels pass through from the outside. The tendency appears to be definitely associated with a propensity to the deposit of excessive fat in the abdomen and elsewhere. Beyond the fact that advancing age has something to do with it, we do not know the cause of this syndrome. We believe that not uncommonly the condition occurs in people who in earlier life had good muscular development and led active, and often athletic, lives.

X-RAY TECHNIQUE

When the diverticulum has protruded beyond, and has therefore lost the support of the muscular coat, it becomes dilated into a circular pouch, varying in size from that of a small shot to a large hazel nut, connected to the lumen of the colon by a narrow neck. The dilated part of the diverticulum is therefore extraluminal, and when filled with barium gives the typical flask-shaped appearance of an opaque rounded shadow projecting beyond the margin of the bowel wall. It is this phenomenon, combined with the fact that these pockets retain the barium long after the lumen of the colon is empty, which distinguishes the radiographic appearances of the condition from any other, and makes it possible to estimate the extent of the disease by *x*-ray examination, of which there are two methods—namely, that of the barium meal and that of the barium enema. The latter is the most efficient procedure. Diverticula can often be recognized by the barium meal method, but it is a very inexact one, and in this paper the radiographic appearances after the injection with a barium enema will be considered alone.

Although much can be written on the technique of a barium enema examination, it is unnecessary to discuss it here; there are two points, however, which are essential to a satisfactory examination, and which receive not infrequently less attention than they deserve. In the first place, immediately prior to the examination, the colon must be thoroughly emptied by means of a high colonic douche. Unless this is done, retained faeces may cause pseudo-filling defects; apart from this, previous emptying of the bowel enables an important prognostic point to be made, for if the diverticula fill with barium (as shown in Figure 1) they are capable of being emptied by the douche. On the other hand, central translucent areas surrounded by thin opaque lines of barium in the diverticula (Fig. 2) indicate that the latter contain inspissated faecal matter or concretions which have not been moved by the douche. This is an extremely important point, both in prognosis and in treatment, since it is the retained faecal matter within the pouches which sets up inflammation in the diverticulum and in the surrounding bowel wall.

Another point which is not often recognized is that *x* ray photographs of the colon are photographs of shadows, and since we are looking for irregularities of the colon outline, a postero-anterior view alone will give a very inadequate picture. In order, therefore, to estimate the extent of the damage accurately, and to see all the diverticula, it is necessary to take photographs in several planes. A photograph in one plane only will miss much that might otherwise be seen. The recto-sigmoidal junction almost invariably, and several inches of the sigmoid colon frequently, are concealed by the upper end of the rectum in a postero-anterior view. The lumina of the hepatic and splenic angles usually overlap one another in this position, and lesions in this region may easily be missed if the radiography and screening are confined to one position. A view in any one plane shows only two borders and one surface; thus the gut must be observed in several planes.

Figures 3, 4, and 5 show consecutive radiograms of the same case made in three different positions. Figure 3, taken in the postero-anterior position, shows an apparently normal colon with, presumably, a sharp "kink" at the junction of the descending and iliac colons. The right oblique position (Fig. 4), however, reveals a well-marked redundant loop of the ascending colon, and shows how easily a lesion in this neighbourhood can be missed if the oblique view is not taken. The left oblique view (Fig. 5), on the other hand, shows that the sharp "kink" in Figure 3 is a gradual curve in the gut with two small diverticula projecting from it on the upper and lower extremities. This was not obvious in either of the other photographs. Finally, both the oblique views make it clear how the recto-sigmoidal junction and much of the sigmoid colon were concealed in the antero-posterior view.

Figures 6 and 7 are radiograms of another case taken in the postero-anterior and left oblique positions respectively. In the postero-anterior view we get no idea of the very marked condition of diverticulosis which is so clearly seen in the left oblique view. These two cases are illustrative of many, and show how dangerous it is to rely on screening and radiographing in one position only.

OBSERVATIONS OF BARIUM ENEMA

In our practice the patient is carefully screened during the injection of the barium enema. By turning the patient to the left the whole length of the sigmoid flexure can be brought into view, and by moving him about, the superimposed shadows of the hepatic and splenic flexures can be separated. The right oblique position enables us to see the posterior wall of the caecum. The rate of

flow of the barium is noted in order to ascertain if there is any delay, as might occur at an obstructed point or narrowing of the lumen. Extramural shadows are also carefully watched for, and if any abnormalities are observed, palpation will indicate whether they correspond to a tumour we can feel or whether the colon at this point is movable or tender. Occasionally the progress of the enema will be brought to a complete standstill for a variable period. Obviously this condition cannot be a complete obstruction, otherwise the patient would not be undergoing an *x*-ray examination. Such a delay in the passage may be due to:

1. Spasm—(*a*) brought about by some intrinsic lesion, or (*b*) due to reflex irritation from some extrinsic lesion, such as gall-stones.

2. Invagination of the mucosa into a constricted portion of the lumen with consequent ball-valve effect.

It is obvious that the presence of a constriction causing delay in the flow of the enema emphasizes the necessity of filling the colon completely and of determining the exact cause of the stoppage. A report that "there is a complete obstruction to the flow of the enema" is of little help. In the majority of such cases obstruction to the flow of the enema may be overcome by lowered pressure and massage. This may have to be continued for some time, but it will be found that eventually the barium passes on and shows the condition of the bowel beyond. Increasing the pressure of the enema in such circumstances is useless, as it tends to increase the spasm. In the rare cases in which massage combined with low pressure does not have the desired effect, the only alternative is to give the patient a barium meal, and when the head of that meal has reached the area in question, to introduce a barium enema to meet it.

The "dual exposure" method has been used by one of us for some years to distinguish between spasmodic and organic narrowing of the colon. Under normal conditions, peristaltic action in the colon is infrequent, but when it is distended with warm fluid, as is the case when a barium enema is being given, peristalsis is much increased. Two radiographic exposures are made on one film at an interval of ten seconds, the patient keeping still and holding his breath during this period. A peristaltic wave passing in this interval will cause the colon to have a double symmetrical outline. When there is any fixation or thickening of the bowel wall a localized single outline will be seen in the affected portion of the colon. Figure 8 shows a dual exposure radiogram of the colon. It will be noted that there is a double outline, except in the area affected by diverticulitis.

DEVELOPMENT OF DIVERTICULA

The earliest stage in the development of diverticula is shown on a radiogram as a serrated margin on the outline of the colon. Dr. Spriggs and Mr. Marxer have described this as a prediverticular stage, and consider that it is inflammatory in origin. Dr. Dukes and ourselves have, however, been able to show that this appearance is not due to inflammation, but is caused by very small and numerous diverticular "buds" in the colonic wall. Figure A below, and Figure 9 in the special plate, if compared, make this very clear; the former is a microscopical section of the colon wall at an early stage in the development of diverticula, and the latter is an *x*-ray photograph of the bowel in a similar condition. Figure 10 shows the next stage, in which the diverticula have broadened out owing to their having passed through the muscular coat. A still later stage showing large diverticula illustrates further development (Fig. 11). Here the diverticula have completely protruded beyond the muscular coat, and, in the absence of supporting structures round them, have become distended to form a typical globular outline. The necks connecting them to the lumen of the bowel are still narrow at the points at which they pass through the muscular coat.

Owing to the arrangement of the muscular fibres diverticula do not occur in the rectum. The commonest situation is the pelvic colon. Diverticulosis may be found throughout the large bowel, and it has occurred in the appendix. All cases start as a simple pouching of the mucosa through the muscular coat without any complicating, or preceding, inflammation. It is the occurrence of inflammation within the walls which is the dangerous element; the presence of diverticula without accompanying inflammation is usually harmless, but we have reason to believe that diverticula unaccompanied by inflammation may occasionally be the cause of very serious mischief. We have seen a case in which an apparently uninflamed

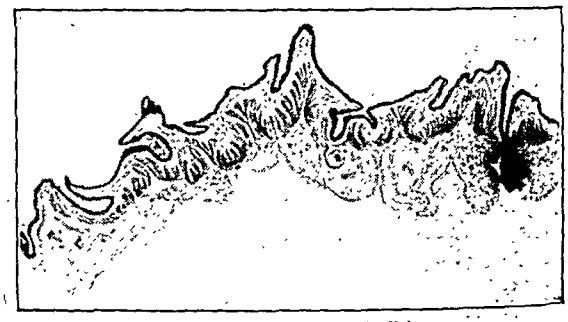

FIG. A.—Early diverticulitis.

diverticulum has suddenly given way by perforation into the peritoneal cavity. In one case of this type the patient had been under observation by both of us for some time. He had extensive diverticulosis of the entire colon, including the appendix (Fig. 12), but had never shown symptoms of it; indeed, the condition was originally discovered by accident. A sudden perforation in one of the diverticula occurred, with disastrous consequences, while he was travelling abroad.

When inflammatory changes have occurred in the walls of the diverticula, as proved by symptoms of pain and tenderness, and by *x*-ray evidence of adhesions and fixation of the bowel wall, the danger is very much greater, and further trouble is inevitable, although with proper care and suitable treatment such trouble may be modified or postponed for long periods. The following is a good example of this:

The patient was a lady, aged 65, who was originally examined because she was thought to be suffering from a neoplasm of the colon. She was very stout, there being a considerable layer of abdominal fat. There was tenderness, inflammation, and an easily felt tumour; the diagnosis was diverticulitis of the pelvic colon. She was carefully treated and kept under observation for two years. She improved very much and remained well, except for occasional slight attacks of pain, but in spite of the treatment she eventually developed obstruction, and a colostomy had to be performed above the damaged area. Since then she has remained in good health.

It has been our custom to interview and *x*-ray our patients every six months. We believe that this practice has proved of value, as it allows us to check treatment and, if possible, to evade perforation or other disasters.

PROGRESS OF THE DISEASE

The mode of progression of the disease varies very much. When inflammation of the colon wall occurs at an early stage in the development of diverticula there is a tendency for the deposition in the bowel wall of fibrous tissue, which in course of time forms a dense stricture.

Under x rays such a condition will show a filling defect, and fixation of the colon. Recently at operation on two cases of this type there was found in both a section of the colon wall, several inches in length, acutely inflamed and densely thickened, with the minute diverticula bulging through the peritoneum. The condition resembled a sort of cellulitis of the bowel wall.

When there is a simple diverticulosis we have noticed that if photographs taken at different periods are compared fresh diverticula can usually be seen, and that some of the previously existing ones are larger. From a study of a number of such cases it seems that, while inflammatory complications may be held in check and often made to retrogress by appropriate treatment, it is not possible to prevent the diverticula from becoming larger or to make them decrease in number unless the faecal contents are deflected from the affected area by a colostomy or short circuit. From the patient's point of view the diverticula do not cause any symptoms as long as inflammatory complications can be avoided. Unfortunately, patients tend to get careless when they have no symptoms, and they think they are quite well and need not continue the treatment. This too often results in acute complications, which may be disastrous. One patient, after being quite well for several years, perforated suddenly while travelling from Paris to London, and died from acute peritonitis. Another patient suddenly developed a perforation into the bladder.

CANCER AND DIVERTICULITIS

Occasionally cancer undoubtedly occurs as a direct result of previously existing diverticulitis. It is, however, a rare complication, and in the only cases met with in which diverticulitis was a direct causal factor there had been extensive inflammatory complications lasting over very many years. One patient had septic sinuses communicating with the colon on the abdominal wall and in the perineum; cancerous changes had occurred in two of the sinuses and had spread to the skin. In another case, an adenocarcinoma had developed and spread on to the abdominal wall along the track of a septic faecal sinus. In a number of patients carcinomatous growth has been found associated with diverticula in the colon. There has been nothing to prove, however, that one condition was a causative factor of the other, and it is more probable that the association was accidental. We have to remember that both diverticula and carcinoma tend to occur at about the same period of human life, and it is therefore not improbable that they may occasionally be found associated in the same individual. The only fact of importance that seems to be established in this connexion is that cancer may sometimes supervene upon a neglected and chronically septic diverticulitis.

TREATMENT

We do not propose in this paper to discuss at length the treatment of diverticula of the colon. We have still very much to learn, and there is ample room for improvement of our methods to-day. At present we can do little, if anything, to prevent the development of diverticula, or to stop their increase either in size or in number. Nevertheless, careful treatment will do much to prevent complications, or, if complications have occurred or are obviously threatening, to obviate such fatal or serious results as perforation into the bladder or peritoneal cavity. Operations for diverticulitis, the inflammation from which has spread to other organs, or has resulted in obstruction, are among the most difficult of surgical procedures. Results are often excellent, however, and patients who have become hopeless invalids can be restored to good health and usefulness. A chronic septic condition, as exists in diverticulitis, is apt in time to be a source of similar trouble in other parts of the body not within the immediate neighbourhood of the lesion. Cases of chronic septic arthritis, phlebitis, thrombosis, empyema, and meningitis, have all come within our experience, while chronic sepsis of the urinary tract is quite commonly associated with the condition.

The best results have been obtained in cases in which the affected portion of the colon could be completely resected and the bowel joined up again; this is the one condition which can be completely cured. We have had several such cases, but unfortunately it is rare to find the lesion sufficiently localized at one portion of the colon to render resection possible.

CONCLUSIONS

1. Diverticula of the colon are not the result of inflammation, and inflammatory conditions of the colon wall which often follow diverticula are always secondary.

2. In spite of treatment, diverticula of the colon, once formed, tend to increase both in size and in number.

3. This increase is often very slow, and may be unaccompanied by symptoms.

4. In the absence of secondary inflammation, diverticula do not, as a rule, cause trouble, but we have reason to believe that exceptionally sudden perforation from the giving way of a diverticulum may occur, apart from any complicating inflammation.

5. A definite diverticulitis is always a very serious lesion, with grave possibilities.

6. A sudden disaster from perforation is not so uncommon as is often supposed.

7 Suppurative diverticulitis is occasionally followed by carcinoma, but it is not a common causal factor of cancer.

8. Operative treatment should not be left until after some grave complication has occurred, but should be timed so as to anticipate and to prevent such disaster.

THE KELOID OVARY*

BY

T. C. CLARE, M.D., F.R.C.S.

SURGEON, LEICESTER ROYAL INFIRMARY; CONSULTING SURGEON, LEICESTER AND LEICESTERSHIRE MATERNITY HOSPITAL

The uterus is the passive partner in the group of sexual organs. Its function is not to originate impulses nor to elaborate hormones, but simply *to be sensitive to* impulses or hormones originated by the more active partners, of which the most prominent, if not actually the most active, are the ovaries. It is important, I think, when considering diseases of the uterus, to bear in mind its state of physiological dependence. It is important because it may possibly lead to the view that symptoms of disease of the uterus—for example, uterine haemorrhage and dysmenorrhoea, associated, perhaps, with definite pathological changes in the endometrium—may be due to a disease or disorder of function originating in the ovary. For instance, the ovary may fail to send any message at all to the uterus, or, on the other hand, it may send so disordered a signal that the endometrium is left, as it were, in a state of uncertainty how to react to it.

* A paper read before the Midland Gynaecological and Obstetrical Society.

In this paper I shall attempt to discuss the part played by ovarian defect in the etiology of excessive menstrual loss associated with little or no gross change in the uterus that can be made out by bimanual examination. This is the condition that used to be called chronic endometritis, or, when there was excessive hyperplasia of the endometrium, endometritis tuberosa vel fungosa ; curettings from these cases, if they show anything more than normal premenstrual endometrium, show more or less hyperplasia without the characteristic appearances of chronic inflammation.

Wilfred Shaw, in his important contribution to the literature of uterine haemorrhage, discusses this type of case, and mentions that it is frequently associated with atrophic changes in the ovaries. He considers that this change in the ovaries is due to an influence exerted on them by the diseased endometrium. I have noticed changes in the ovary in this type of case, and I want to suggest a different and, as it seems to me, more likely explanation.

The ovary is unique among the organs of the body in two respects—one physiological, the other pathological. The physiological peculiarity is that it is the only organ which is normally subject to trauma and consequent reparatory changes. The trauma consists of the lesion of the surface that occurs at the time of the rupture of the follicle and the formation of the corpus luteum. The reparatory process is the little scar, consisting of fibrous tissue, by which the surface lesion is repaired. Nowhere else in the body, except in the umbilicus, is there such a thing as normal scar tissue. The process of healing of this little normal lesion is the same as that in any other wound.

KRUKENBERG TUMOURS OF THE OVARY

The pathological peculiarity of the ovary is the occurrence in it of the remarkable bilateral carcinomatous growths known as Krukenberg tumours, found nearly always, if not invariably, in association with carcinoma of the stomach or large bowel. Consideration of these tumours will lead me into a digression from the main argument, but I would like to make a suggestion as to the origin of these tumours.

We may, I think, regard it as extremely probable, though not inevitable, that, if in any organ, or indeed in any object at all, we find two unique features, these peculiarities will be found to be connected in some way. One will depend on the other and could not exist without the other. If this argument is accepted as logical, we may seek to find some association between the two features of the ovary which make it unique—its normal liability to trauma and the occurrence of these remarkable tumours.

There are two current explanations of the Krukenberg tumours. One is that cancer cells become detached from the primary growth and are grafted on the ovary after falling through the peritoneal cavity. This does not explain why the ovaries should be the only organs in the abdomen to be affected, or why cancer cells are found in the deeper parts of the ovary and not on the surface. The other view is that the ovary is invaded by lymphatic spread via the lumbar glands. This also is difficult to accept because it does not account for the absence of infiltration of other lymphatics (for even glands in close relation to the primary growth are often not involved in these cases), or for the fact that the tumours are bilateral.

The first hypothesis, however, becomes more easy of acceptance, and indeed, I suggest, affords an entirely satisfaction explanation, if we employ the logical argument that this unique pathological phenomenon is likely to be connected with the unique physiological one—namely, the periodical occurrence of an open wound on the surface of the ovary. Cancer cells are delicate weakly cells, more vulnerable than other cells (for example, to x rays and radium), and they will perish if they fail to find a suitable nidus. The surface of the peritoneum does not afford a suitable resting-place, nor would the ovary, if its surface were unbroken. But if it should happen that cancer cells become detached (and it must be a rare occurrence, corresponding to the rarity of these tumours) and fall into the cavity formed by a recently ruptured follicle, they will find a place where conditions are favourable for survival. The wound is quickly healed over by scar tissue, which forms, as fibrous tissue always does, an insuperable barrier to the spread of cancerous growth. The path of least resistance (always taken by cancer cells) is downwards into the substance of the ovary, along the track taken by the ripening follicle in its ascent to the surface. Hence the growth takes place in the substance of the ovary, not on the surface.

The hypothesis that Krukenberg tumours originate from the implantation of cancer cells in a ruptured follicle was suggested by Schauta. If it is valid it will affect our view of the prognosis of these cases. We shall not regard them as having the same significance as secondary growths spreading by lymphatic permeation. If they are removed before the growth has spread beyond the ovaries, and if the primary growth can be removed entirely, the prognosis should be good compared with that, for instance, after removal of a growth of the breast and affected axillary glands.

I will conclude this digression by recalling that there is a third peculiarity of the ovary: it is the only organ in the abdomen that is uncovered by peritoneum. The connexion of this peculiarity with the function of ovulation and also, if this hypothesis is correct, with the occurrence of the Krukenberg tumour, is obvious.

To return now to the normal ovary and in particular to the process of repair of the lesion made by the rupture of the follicle. This little wound, like other wounds, is repaired by the growth of connective tissue cells in the form of scar tissue. In course of time the smooth surface found at the time of puberty is gradually changed to a more or less corrugated surface, patchy at first, but later becoming uniform. Normally there is no marked change in the consistence of the ovary ; the fibrous scar tissue is thin and does not convey the impression of hardness. Quite often, however, one finds here and there, on the surface of the ovary, areas or patches of exceptional hardness, suggesting that in these areas fibrous tissue has been laid down in a greater degree than usual. Less often the hard fibrous patches are so numerous and continuous that the ovary has almost the hardness of wood, though there are generally softer parts where cystic dilatations of follicles project on the surface. Microscopical sections of these ovaries demonstrate the excess of fibrous tissue.

The process of repair in all tissues depends on the existence of a regenerative capacity. This function of regeneration varies in different tissues and in different individuals. Some tissues have a very perfect capacity of regeneration, for instance the skin and mucous membranes generally. Lesions of these tissues, when they heal, show little or no evidence of the former injury. On the other hand, lesions of highly organized tissues, such as muscle and the cells of the central nervous system, show little or no evidence of any regenerative capacity ; injuries to these tissues are repaired by connective tissue. But the regenerative capacity varies not only in different tissues but also in different individuals. A good example of this is seen in the repair of fracture of bones ; in some individuals repair is delayed far beyond the normal ; in a few there is practically no reparative process at all. Even in the simplest form of the regenerative process, scar formation from growth of connective

tissue, there are individual variations. Thus it is not uncommon to find, especially in slowly healing scars, a tendency to overgrowth of fibrous tissue. This condition we speak of as keloid.

The excessive formation of fibrous tissue found sometimes in the ovary may be looked upon, I suggest, as a form of keloid overgrowth of fibrous tissue. It is a keloid scar formed as a disordered or exaggerated regenerative process in the healing of the scar left by the ruptured follicle. It is not a disease in the sense that it is a reaction to a morbid extrinsic factor, such as bacterial infection. There is no evidence of inflammation, and it is incorrect to speak of the condition as chronic ovaritis. It is a disease, however, in the sense that it is the cause of symptoms of disease. I shall endeavour to show how such a condition is able to produce pathological manifestations.

Whatever theory we may hold as to the interaction of the various sexual hormones in the initiation and regulation of the menstrual cycle, it will, I think, be agreed that the liquor folliculi contains some substance that is essentially and perhaps solely concerned with the activation of the endometrium. It may or may not be necessary for an ovum to be discharged ; it may or may not be necessary for a corpus luteum to be formed ; but without the hormone elaborated in the liquor folliculi the endometrium remains inactive. Perhaps we may go so far as to say that the complete cycle of ovulation, including the formation and atrophy of the corpus luteum, is necessary for the normal cycle ending in complete shedding of the menstrual decidua. If the ripe follicle comes near the surface of the ovary, but, for some reason, does not rupture the surface, then no corpus luteum is formed, or rather an incomplete or abortive corpus luteum results, projecting, as we sometimes see it, on the surface of the ovary as a sort of polypoid excrescence ; no haemorrhage has taken place into it.

It is most unlikely that such an abortive corpus luteum will function entirely like a normal one ; it may fail to function at all ; but it is more likely that the granulosa cells, formed for the special purpose of secreting a hormone whose object is to maintain the endometrium in its thickened state, to prevent its disintegration, and so to " prepare a bed " for the ovum, should at any rate make some attempt to exercise their function. We are justified, I think, in making the assumption that the signal sent by the abortive or imperfect corpus luteum to the uterus will be an imperfect signal ; it will be transmitted to the endometrium, but, if I may put it so, it will not be so readily understood, with the result that the endometrium is left in a state of uncertainty as to whether it is expected to disintegrate or to persist. It may happen, therefore, that the discharge of the menstrual decidua is incomplete, and though haemorrhage ceases at the normal time, some cells that should have been discharged remain when the endometrium returns to its post-menstrual condition. The result will be that in course of time there is, by repetition of this process, a considerable hyperplasia of endometrium, which never returns to its normal state. The hyperplasia may proceed so far that the endometrium is brought to the condition we are familiar with as endometritis tuberosa vel fungosa. Long before the changes in the endometrium have advanced to this degree of hypertrophy there will be increased menstrual loss, becoming continuous in those cases where the hypertrophy is so marked that the polypoid or fungous overgrowth has practically the effect of a tumour of the endometrium.

It is in cases of this kind, where excessive menstrual loss, sometimes prolonged or continuous, is associated, not with gross enlargement of the uterus, but with hypertrophy of the endometrium, that I have found the marked degree of induration of the ovaries described above. Where the induration is extreme, it seems impossible that the wonderful mechanism whereby the ripening follicle is conveyed from the deeper parts of the ovary to the surface can be effective. The dense fibrous tissue offers an insuperable resistance. The liquor folliculi is there, and its hormone is presumably absorbed, for menstruation goes on, but ovulation does not take place and no corpus luteum is formed. In the less-marked cases the follicle may get near the surface but fail to penetrate the surface layer of keloid tissue, though there may be parts of the ovary where there is little or no thickening and ovulation can take place normally in these parts. So it would seem to depend on chance, in these cases of patchy induration, whether ovulation is normal or incomplete.

I suggest that it is wrong to regard the sclerosis of the ovary as secondary to changes in the endometrium, and that such a view of the pathology of the condition is at variance with the teachings of physiology that it is the ovary which influences the uterus, and not vice versa. The primary change, I suggest, is in the ovary, and it consists of a failure of the regenerative process, whereby an excess of fibrous tissue, in other words keloid tissue, takes the place of the small fibrous scar that normally closes the stigma.

TREATMENT

It is a sound general principle of treatment to seek for the cause of the disease and remove it. In the type of case we are considering, however, there are obvious disadvantages in adhering too closely to this principle ; for assuming for the moment that the condition I have described is the actual cause, we should, logically, be forced to advocate removal, or inactivation, of the ovaries —or, at least, of the most obviously affected ovary. There is the possibility, certainly, that in cases where the fibrosis is not too far advanced a course of treatment by thyroid extract might have the effect, as it undoubtedly has in some other situations—for example, in Dupuytren's contraction—of softening the excess of fibrous tissue and facilitating its absorption. Though I have no proof that thyroid extract can act in this way on the sclerosed ovary, I suggest that the beneficial results of thyroid therapy in some cases of uterine haemorrhage in young women may possibly be due to the fibrolytic action of thyroid extract. Most of the cases in which this type of haemorrhage is met with, however, are not those of young women. I have come across a few cases in young women where small patches of dense induration in an ovary are associated with dysmenorrhoea and considerable but not excessive loss, but much more often the patients are over the age of 36. At this age it is probably hopeless to attempt to deal with the cause of the disease, and removal of the ovaries is hardly to be considered. Nor am I in favour of inactivating the ovaries by *x*-ray treatment. It remains, therefore, to treat and, if this is unsuccessful, to sacrifice the innocent partner in the pathological complex—namely, the uterus—to treat the symptoms rather than remove the source of the disease, because almost any sort of ovary is better than none at all. I believe that on pathological grounds hysterectomy is the best treatment in all these cases, but there are other factors to be considered besides pathology.

The uterus deserves and receives more consideration than the appendix or gall-bladder. Therefore one's first thought, as regards treatment, is either curetting alone or curetting followed by radium. I think curetting is worth doing, not only for its diagnostic usefulness, but because the removal of hyperplastic endometrium is generally followed by temporary improvement, and occasionally the relief is permanent. The curette removes the

excess of endometrium which should have been removed by the disintegrating effect of menstruation. As the accumulation of menstrual decidua, due to ovarian disease, is generally a slow process, it may happen, in women approaching the menopause, that relief from symptoms after a single curetting lasts until the menstrual function comes to an end.

In many cases, however, and probably in most, the relief obtained by curetting is only temporary, not more than a few months. If serious haemorrhage recurs after a single curetting I believe hysterectomy should be performed. All due consideration has been given to the peculiar position of the uterus, and it should no longer be regarded as differing from a diseased appendix or gall-bladder. It should simply be regarded as a source of ill-health and perhaps danger, and should be removed. I would go further and say that, even apart from ill-health and danger, if her uterus has become a nuisance to a woman, on account of losses prolonged and severe enough to interfere with her enjoyment of life and with her career if she is in business, even though the general health may not be greatly affected, hysterectomy is justified if curetting has failed. I have no experience of radium in these patients, though I should be inclined to use it if hysterectomy is, for some reason, inadvisable. In parous women without gross enlargement of the uterus there is a good deal to be said for vaginal hysterectomy in this type of case. Though the operation is undoubtedly more difficult, I believe the shock is less, and the period of convalescence shorter.

In conclusion, I should like to refer again to Mr. Wilfred Shaw's valuable paper on uterine haemorrhage,[1] and especially to the section on metropathia haemorrhagica, and to criticize, not his findings, pathological or clinical, but certain of his deductions. He refers to the association of a polypoid condition of the endometrium with atrophic ovaries, one of which is generally cystic. He regards the hyperplasia of the endometrium as evidence of over-activity of the endometrium and the shrunken condition of the ovaries as evidence of diminished activity of the ovaries. He concludes that the polypoid endometrium reacts on the ovaries to produce an inhibition of follicle ripening, or of ovulation, or of full formation of the corpus luteum ; the ovaries, in turn, responding by producing continuously a toxin, identical in type with that causing the disintegration of the premenstrual endometrium in normal menstruation. And he regards as proof of the inhibitory action of the polypoid endometrium the fact that, in some cases, curetting is followed by a return to normal menstruation.

In criticism of these findings I would say: (1) We have strong evidence that the ovaries control the uterus, but none at all that the uterus can influence the ovaries, or that the uterus has any action except to react to hormonic signals from the ovaries. (2) Hyperplasia of the endometrium is not evidence of activity of the endometrium. It is much more reasonably to be regarded as evidence of a defect in its response to ovarian signals, or, equally logically but more probably, a deficiency in the hormone itself, either in quality or in quantity. The thickening of the endometrium is, I maintain, to be regarded rather as a failure of premenstrual endometrium to be completely shed than as a true hypertrophy of endometrial tissue. (3) Curetting acts by removing the excess of endometrium, and in that way imitates the action of the corpus luteum, or of whatever hormone is responsible for disintegration. As normal ovulation may be possible in unaffected parts of an otherwise diseased ovary, menstruation may go on normally once the endometrium has been made smooth by the curette. (4) The size of the ovary is no criterion of the activity of the function of ovulation. The presence of a ripening follicle will ensure the first part of the menstrual cycle—namely, the thickening of the endometrium. Incompleteness of ovulation—that is, failure or delay of the stage of corpus luteum formation—will be followed by incomplete disintegration, and consequent retention of degenerate endometrial cells. In some cases I believe this incompleteness of ovulation is due to the dense fibrous (keloid) covering of the ovary.

References to the connexion between pathological conditions of the ovary and menorrhagia are not infrequent in the literature ; the earliest of which I am aware occurs in a paper by C. J. Bond,[2] in which the connexion is very convincingly established.

THE INTERPRETATION OF PAIN IN INFANCY*

BY

WILFRID SHELDON, M.D., M.R.C.P.

JUNIOR PHYSICIAN TO THE CHILDREN'S DEPARTMENT, KING'S COLLEGE HOSPITAL

Of all the symptoms from which man suffers none is so insistent of recognition as pain, nor is any of greater value to the doctor in helping him to make a diagnosis. The adult is in the fortunate position of being able to give an accurate description of his pains, and to indicate their locality with sufficient precision. The young child, once he has acquired the power of conversation, can also tell us when he feels pain, although a fuller analysis may be beyond him, as, for example, when he complains of headache but localizes it at the umbilicus! Often in the baby the presence of pain can only be suspected after careful observation, and if a parent is convinced that a child is suffering in this way it is generally foolhardy of the doctor to cast such testimony aside. By taking a careful history, followed by an attentive watch and thorough examination of the infant, the characters of its pains and the site of their occurrence can be determined.

CHIEF EVIDENCES OF PAIN

The commonest effect of pain on a baby is to make him cry, and much help is to be gained from a study of the characters of this expression. Pain is by no means the only cause of a baby's crying ; hunger, cold, a soiled napkin, or simply a state of boredom, are also contributory factors. It is not until the child exercises his will that crying due to temper makes its appearance ; this is a cause which is exceptional in those under 6 months of age.

The features which should always be noted are whether the cry is intermittent or continuous, whether it is a piteous wailing or a short, sharp scream, and whether it occurs at any particular time of the day or night. Does it bear any relation to the times of feeding, being relieved or aggravated by food? Does it cease after the belching of a good deal of wind? The history may show that the pain only accompanies certain physiological performances such as sucking, micturition, or defaecation. Under the stress of severe pain the infant may not cry because he is holding his breath, as frequently happens in severe colic.

The baby's posture during the bouts of pain should be carefully noted. It may be that the hips are flexed to bring the thighs up on to the abdomen, while the arms may be bent, with the elbows firmly pressed against the sides. In other cases, the infant may become rigidly extended, with arched back, so that he supports himself

* Abstract of an address delivered before the Hampstead Division of the British Medical Association.

by his head and heels. Finally, on clinical examination there may be found areas of distinct tenderness associated with pain, indicating its localization.

GASTRO-INTESTINAL PAIN

The commonest cause of gastro-intestinal pain is some error connected with the diet, and the fault can generally be traced to one of three things—namely, the amount of food may be too great for the infant's digestive capacity, the diet may be badly constituted, or there may be some flaw in the method of giving the food. Simple underfeeding does not of itself give rise to pain, excepting that accounted for by the pangs of hunger. The pain of indigestion has a direct relation to meals, and if it arises in the stomach it will generally be manifest within a few minutes of a feed. If the cause lies further down the intestinal tract, the evidence of pain is likely to appear from half an hour to an hour after food has been given. If the fault continues unchecked, chronic indigestion will follow and pain will become continuous, lasting from one meal-time until the next. Simple overfilling of the stomach with food is not a common cause of pain in infancy, partly because the infant's stomach is a readily distensible organ, and partly because any attempt to overdistend it is countered by vomiting, a process which is much less disturbing in infancy than in later life. The old custom of winding about a yard of flannel round the baby's abdomen, and so preventing the natural postprandial epigastric fullness, was often a cause of discomfort and pain; fortunately, this practice is becoming less common.

Errors of diet lead to excessive peristalsis, and culminate in painful colicky contractions. The pain in these cases is generally intermittent. At intervals of a few minutes the baby begins to cry, draws his knees up on the abdomen, and presses his elbows into the sides; this attitude is maintained for two or three minutes while the baby cries vigorously, then the attack subsides. During the attack, relief may be given by keeping up a steady pressure with the warmed hand on the abdomen, or, more easily, by turning the baby over and allowing him to lie on his face, with the abdomen supported across the palm of the hand. The position of the infant in these attacks is exactly comparable to that of the adult in similar circumstances. We may briefly consider, below, the various dietetic errors which may culminate in colic. Most commonly there is an excess of gas in the stomach or intestine. In the stomach this gas will be excess air swallowed with the food, and probably it is a result of too big or too small a hole in the teat of the bottle, or of the baby being allowed to suck at an empty breast. When there is excessive gas in the intestine, some of it may have been passed on from the stomach, but the passage of large amounts of flatus per rectum is more frequently due to too much sugar in the diet, leading to intestinal fermentation, with the liberation of carbonic acid gas. Colicky pain may also result from irritation of the intestine by large, tough casein curds, or, less frequently, by fat curds. In the management of these cases the fault in the diet must first of all be corrected. Small doses of chloral (1/2 to 1 grain), given just before the feed, are useful, helping the child to drop off to sleep after the meal, and ensuring a period of peaceful digestion. Vigorous jogging of the baby is quite unnecessary; the simple procedure of holding the infant upright against the shoulder and patting the back is all that is required to release a large bubble of air imprisoned in the stomach.

Stomatitis

We are sometimes told that a baby sucks from the breast or bottle for a minute or two, and then cries and refuses to continue sucking. It may be that the breast is empty or that the hole in the teat is so small that the infant cannot draw milk, and turns away disgusted. When, however, a child has previously been making satisfactory progress, these symptoms are often due to painful conditions inside the mouth, which should be carefully examined in a good light. There may be a simple catarrhal stomatitis, or a condition of thrush affecting the tongue and the inside of the cheeks. Numerous small shallow ulcers may be found in the mouth. Fortunately the gangrenous form of stomatitis is rare, for it is accompanied by grave toxaemia and a high mortality. In the management of these cases, the milk, well cooled, should be given from a spoon. The feeding utensils must be properly sterilized, and the mouth cleansed before and after each feed by gently swabbing with borax and glycerin, or with a weak solution of hydrogen peroxide.

Constipation

A mother sometimes complains that her infant screams when he is having a motion. The pain is generally the result of constipation. The infant strains and goes red in the face; eventually, if the effort is successful, a hard scybalum is passed, often leaving the baby pallid and exhausted. A diet rich in fat, such as a full-cream dried milk food, combined, perhaps, with insufficient sugar, often leads to this state, and a proper adjustment of the food may be all that is required. A small teaspoonful of magnesia, or the same amount of paraffin, given once a day, will be effective in other cases, and will not upset the digestion. Occasionally, and oftener in females, there is associated with the constipation, spasm of the anal sphincter, which by its rigid contraction maintains and intensifies the state of constipation. Anal spasm can only be detected by performing a rectal examination. In the normal infant gentle but steady pressure with the well-greased forefinger will enable it to pass without difficulty into the rectum, but in the presence of anal spasm the anal orifice is much smaller, and the sphincter feels like a tightly constricting band round the finger. Digital examination of the rectum stretches the sphincter, and may suffice to cure the condition.

Anal Fissure

Another cause of painful defaecation is the presence of a fissure at the anus. This is not uncommon in babies; and is generally due to tearing of the mucosa during the passage of hard faecal masses, which may be streaked with a little bright blood. The fissure is usually small, and can only be seen when the anal folds are held gently apart. It may lead to spasm of the anus, which increases the constipation, and in this way a vicious circle is set up. Defaecation is resisted by the baby, who screams, arches his back, and compresses his buttocks together. Treatment consists in softening the stool with paraffin, while the fissure may be smeared with an ointment of silver nitrate (1 per cent.). Stretching the anal sphincter with the finger may also lead to a cure.

Intestinal Obstruction

In a baby previously healthy, the sudden onset of screaming and intestinal colic, with attacks recurring every few minutes, is suggestive of an acute intussusception; the passage of a little blood in the stool, and the typical sausage-shaped tumour in the abdomen, would confirm our suspicions. The rarer causes of obstruction, such as volvulus or strangulation by peritoneal bands and the very rare cases of appendicitis in infancy, are marked by sudden pain, vomiting, and constipation, followed by abdominal distension, and collapse of the child. These symptoms are also encountered in strangulated hernia, but in addition the tender swelling in one groin indicates the true nature of the case.

EARACHE

Earache is one of the most frequently overlooked causes of pain in infancy. Owing to the short length of the Eustachian tube in the infant, mild catarrhal infections of the nasopharynx, producing little disturbance of health, and generally passing unsuspected, are within easy reach of the middle ear. Screaming and irritability, with fever and often a mild diarrhoea in a young child, should lead to a careful examination of the ears. As in gastro-intestinal colic, the screaming of earache may occur in bouts, but can be distinguished by the posture of the baby. During the exacerbations of earache the infant throws himself into an attitude of rigid extension, arching his back and retracting his head. This attitude will sometimes be maintained for several hours or even for days, and may give rise to suspicions of meningitis. Not infrequently the pain of earache is worse at night, leading to considerable disturbance of sleep. Further indication of the seat of the trouble may be given if the baby constantly pulls and worries at his ears, and rolls and bangs his head on the pillow. On account of the minuteness of the parts, examination of the tympanic membrane in a small baby is not easy. Using a good light and a small-bored speculum, we may note that the normal grey, shiny appearance of the drum is replaced by one which is dull grey or faintly pink ; dilated vessels may be seen coursing along the handle of the malleus. The infection is generally bilateral. In severe cases, with head retraction, high fever, and perhaps convulsions, with the drum bulging and under pressure, rapid relief can be brought about by paracentesis. Although pus may not appear for a day or two, the relief of tension will be followed by a sharp fall in temperature and cessation of pain. It is much better to do a paracentesis, which will heal in a few days, than to wait for the drum to burst, for discharge of pus may then persist for months. One or two drops of a solution of 2½ per cent. carbolic acid in 50 per cent. glycerin run into the ear will also diminish the pain. Warm fomentations are particularly useful at night when the baby cannot sleep. They should be large enough to cover the ears amply, and are most easily kept in position by using a tight bonnet instead of a bandage. Small doses of chloral also help to reduce the pain.

TEETHING

Teething is too often made the excuse for many of the upsets and pains of infancy, but nevertheless I have no doubt that this physiological process does, in some babies, occasion much discomfort and pain. Great irritability and screaming, refusal of food, fever, and even photophobia may all subside with the eruption of a canine or molar tooth.

INTRACRANIAL DISEASE

This may be the cause of considerable pain in early life. Attacks of sharp screaming may occur in the first stages of post-basic meningitis, sudden piercing screams are not uncommon in the irritable stage which ushers in tuberculous meningitis, and movement of a child whose head is rapidly enlarging from hydrocephalus may cause loud crying.

URINARY PAIN

Pain arising from the urinary tract is not uncommon in infancy. We may sometimes be misled by a mother's statement that her baby screams every time he passes water, for it may be that he passes water every time he screams—a very different matter. In infancy the bladder is more an abdominal than a pelvic organ, and it is quite likely that the rigid contraction of the abdominal wall when a baby is screaming will tend to compress the bladder and lead to urination, just as an infant will often micturate when the hypogastrium is being palpated. In male infants a common cause of screaming during micturition is the presence of a small ulcer at the urinary meatus. It is commoner in the circumcised, and is partly the outcome of the glans chafing against a rough napkin. The ulcer is often minute, and close examination is required in order that it may be discovered. The exudate from the ulcer dries into a scab over the meatus, and the bursting open of this seal makes micturition painful, and a few drops of blood may precede the passage of urine. Treatment consists in covering the glans with a piece of gauze spread with vaseline, and in paying careful attention to changing the napkins as often as necessary to keep the parts dry. It is also useful to rinse the napkins in a strong boric solution before they are dried. Painful micturition may sometimes be due to a highly acid urine, particularly if the urine comes in contact with excoriated buttocks. This may happen from overfeeding with carbohydrate or fat, and may be relieved by modifying the diet, and by giving small doses of potassium citrate. The passage of large numbers of crystals in the urine may also lead to considerable dysuria. The commonest offenders are uric acid crystals, which are excreted abundantly during the first few weeks of life, and may give rise to renal colic, with attacks of screaming and vomiting. More rarely the passage of oxalate crystals accounts for the symptoms. Relief is given by increasing the intake of fluid and by giving alkalis. The passage of calculi rarely occurs until later on in childhood.

Pyelitis

Acute infection of the urinary apparatus, and pyelitis in particular, is a frequent cause of pain in infancy, and like otitis media it is often overlooked. This is due partly to the difficulty there may be in collecting a specimen of urine from a baby, and partly to the fact that pyelitis, being commoner in girls, tends to make us less watchful for the condition in male babies. There may be nothing characteristic about the pain of pyelitis beyond the sustained irritability of the infant, and therefore it should be a rule that, in any infant who has a sudden illness with fever, irritability, and perhaps rigors, for which no cause can be found, a sample of urine should be obtained and examined for pus. Sometimes the course of pyelitis may be punctuated by attacks lasting for a few minutes, in which the infant screams, stiffens, and appears anguished, then turns pallid and becomes collapsed. These bouts of pain are probably due to the passage of clots of pus down the ureters. Apart from the urine, examination of the baby suffering from pyelitis is generally negative, but palpation may show that the infant is tender in one or both loins, wincing when these areas are touched. The urine which is examined for pus need not be sterile. Gentle pressure over the hypogastrium may be sufficient to start micturition. Another method is to lay the infant on mackintosh sheeting spread over pillows. The centre of the sheet is then pushed down between the pillows so that when the baby passes urine this will collect in the lowest portion of the mackintosh. In the male baby free from balanitis or meatal ulceration there should be no pus cells in the uncentrifugalized urine ; in girls more than two pus cells in the 1/6 microscopic field should be regarded as abnormal.

THORACIC PAIN

Thoracic pain in the infant is indefinite, and difficult to assess. In lobar and broncho-pneumonia the rapidity and shallowness of the respirations will reflect to some extent the pain resulting from involvement of the pleura, as will the feebleness of the cry owing to the pain of

drawing a deep breath. Displacement of the neighbouring structures associated with large accumulations of pus in the pleura may also be painful.

PAIN IN THE LIMBS

Pain in the limbs is shown in two ways: first, the painful limb is moved less than the other limbs, and may be motionless, and, secondly, any attempts to move the limb provoke crying. When an infant has pain in the limbs trauma must first be excluded. There may be a history of injury, and examination may show bruising of the soft parts; but the more severe lesions, such as fracture or separation of an epiphysis, may only be detected after a most careful clinical scrutiny aided by *x*-ray examination. Trauma, however, is not a common cause of pain in infancy.

Apart from trauma, pain in one or more limbs in an infant under 6 months of age should make us think of syphilitic epiphysitis. In this condition the arms are most commonly affected, and the process may be confined to one limb, which is so immobile that the term "syphilitic pseudo-paralysis" has been given to it. There may be additional evidence of syphilis in the baby, such as condylomata about the anus or mouth, or a history of snuffles or of rashes affecting particularly the palms of the hands and soles of the feet. *X*-ray examination will show inflammatory swelling of the shaft and epiphysis of the affected bone. Under treatment with mercury the pseudo-paralysis will pass off in ten days or so.

Infantile scurvy is the dominating cause of limb pains in the period from the sixth to the eighteenth month of life. Owing to the subperiosteal effusions of blood the pain and tenderness of the limbs is intense, often making the baby cry from anticipated pain before it is actually touched. The observant mother will notice the baby's sensitiveness at an early stage, especially when she bathes her child, a history which is most suggestive of scurvy. The legs are more commonly affected than the arms, and the baby adopts a characteristic attitude, the hips being abducted and externally rotated and the knees bent. There may be visible swelling, most frequently just above or below the knee; in other cases the swelling can only be detected by gentle palpation. Palpation, however, causes such exquisite pain that one first looks for other signs of scurvy, such as purplish swelling of the gums around the erupted teeth, scorbutic beading of the ribs, orbital haemorrhages, and the presence of red blood cells in the urine. Once the diagnosis is made, relief of the acute symptoms can be brought about in two or three days by giving the antiscorbutic vitamin in the diet. Fresh unboiled cows' milk, fresh fruit juice, and potato made into a cream with milk are all effective, and may be combined in order to expedite the cure. Meanwhile the baby should be moved as little as possible in order to limit the pain, and should only be lifted when his napkins require to be changed.

Two conditions remain which may give severe pain in the limbs. These are acute osteomyelitis and acute poliomyelitis. The onset of osteomyelitis is sudden, and is accompanied by pain and tenderness in the affected limb, the temperature rises to 103° or 104°, and the child rapidly becomes pallid and profoundly toxic. The morbid appearance of the child gives the first clue in distinguishing this condition from scurvy. Later the tissues over the affected bone become swollen and oedematous, and the skin hot and red. As soon as the diagnosis is made the bone abscess should be opened and drained. With this condition we may group the cases of acute suppurative arthritis, often involving several joints, which may arise during infancy, and may lead to swelling of the joints with much pain and loss of movement.

Acute poliomyelitis may occur quite early in the first year of life, and the affected limb or limbs may be acutely tender for the first few days. There is, however, no swelling of the limb, and after a few days wasting becomes apparent. Furthermore, the loss of movement is more profound than in scurvy or epiphysitis, for in these conditions slight movements of the joints can be provoked by stimulation, but in the early stages of poliomyelitis the whole of the affected limb remains motionless.

A CASE OF GLOSSOPHARYNGEAL NEURALGIA

BY

J. P. MARTIN, M.D., F.R.C.P.

PHYSICIAN TO OUT-PATIENTS, NATIONAL HOSPITAL, QUEEN SQUARE

Tic douloureux affecting the glossopharyngeal nerve is a rare condition. The only cases of it that have been recorded in this country are three described by Dr. Wilfred Harris,[1] but about twenty cases have been reported in America since the publication of Harris's first description of it in 1921.[2]

Its recognition is important, because it is likely to be mistaken for trigeminal neuralgia of unusual distribution, and treatment may be misdirected in consequence. In a large proportion of the recorded cases, the patient has been subjected without benefit to an alcoholic injection of the third division of the trigeminal nerve, or to an operation on the Gasserian ganglion before the true condition present has been recognized.

The following case is the first that has come within my experience.

A man, aged 61, was referred to me on October 3rd, 1930. He complained that when he swallowed he had a "burning" pain in the left side of the throat and an intense stabbing pain deep within the left ear. Each spasm of pain lasted only a few seconds. The spasms varied greatly in frequency and severity, but when they were prevalent he had "a dread of meal times."

Inquiry brought out the following additional facts. The trouble began about eight years previously. At that time the patient felt "a prick" in the left ear when he swallowed. This disappeared for months at a time. After a considerable period it began to be a rather sharp pain.

About 1925, when having a drink of stout, he had an attack of the most intense pain in the ear. It lasted only for a few seconds, but he "thought he would go mad." This was the first attack of intense pain; few subsequent spasms have been as severe. He attended the throat department of one of the large hospitals, and was examined, but nothing abnormal was discovered, and no treatment was given. Thereafter severe pains became not uncommon. By this time he had noticed that the pain in the ear was accompanied by a "burning feeling"—not intense—towards the back of the throat on the left side. The attacks used to make him bend his head over to the left and draw the left shoulder up. The pain was nearly always brought on by swallowing; both solids and fluids would cause it, and any large bolus of food was sure to bring on a spasm: swallowing saliva sometimes caused the pain, and talking sometimes seemed to bring it on. The left side of the throat felt dry, especially at night, and this feeling made him "clear his throat" frequently.

In 1926 he was examined at Golden Square Hospital by a laryngologist, who raised the possibility of a growth in the throat, and took the precaution of examining him again, under a general anaesthetic. Nothing abnormal, however, was discovered in the throat. The following year he saw another laryngologist, who said his tonsils were septic and advised their removal. Tonsillectomy was performed, and for some time afterwards the patient had very little pain.

Recently the pain has not been of the maximum severity. It is brought on, above all, by swallowing, and nearly all the attacks are at meal times. Swallowing saliva and talking cause lesser attacks. During swallowing, when the bolus "gets a certain distance into the throat," the pain is felt. The "burning" pain in the throat has now spread further forward, involving the left faucial arch. The worst pain is within the ear. Some pain is felt in the external auditory meatus and spreads over a small semicircular area within the auricle behind the meatus. When the spasms have been frequent and severe, this area remains sensitive continuously, and touching it excites the pain: at such times the patient does not dare to wash the left auricle. This condition may continue for a week or so at a time. There has been no pain on the back of the auricle or on the side of the face. With severe spasms there is a great increase in the flow of saliva. This is always accompanied by intense burning pain in the left side of the throat.

Discussion of Symptoms

The area within the pharynx to which the patient refers the "burning" pain receives its sensory nerve supply from the main division of the glossopharyngeal nerve. The middle ear is supplied by the tympanic branch of the same nerve, and it is doubtless this branch that is responsible for the patient's worst pain. A twig from the tympanic branch joins the auricular branch of the vagus which supplies the area in and behind the external auditory meatus, where the patient has occasional pain. The glossopharyngeal nerve is the secretory nerve to the parotid, and it is presumably to excitation of the parotid branches that the salivation accompanying his more severe spasms is due. All the symptoms are thus referable to the distribution of the glossopharyngeal nerve.

Physical examination of the patient on two occasions has revealed no abnormal signs within the province of the glossopharyngeal nerve, in other parts of the nervous system, in the throat or ear, or in the neck.

The typical distribution of the pain in glossopharyngeal neuralgia is in the pharynx, ear, and auricle. In some of the recorded instances the pain radiated behind the auricle and also in front of it down to the angle of the mandible. Pain behind the auricle may be attributed to excitation of the auricular branch of the vagus, but pain anterior to the auricle and down to the angle of the mandible is not easily accounted for unless we suppose either that some of the parotid branches are sensory, or else that with the neuralgia there is an overflow of stimuli within the common somatic sensory nucleus in the medulla, giving rise to a sensation of pain referred to this part of the face.

In many of the recorded cases frequent "clearing the throat" or "hacking" is referred to. This symptom, which was not pronounced in my case, arises secondarily from the feeling of discomfort in the throat—"as if there was something there." Clearing the throat evidently gives the patient some relief.

Diagnosis

In the first place it has to be determined that the pain complained of is in the distribution of the glossopharyngeal nerve, and, in the second place, it must, as far as possible, be determined that it is an "idiopathic" neuralgia.

The distribution of the neuralgia has already been sufficiently referred to. The similar well-known neuralgia of the third division of the trigeminal nerve affects the lower jaw and tongue, and may involve the lobe of the auricle. Geniculate neuralgia is a rare condition which causes a pain in the ear usually associated with facial palsy; in most cases it is preceded by herpes in the ear. Strict attention to the site of the pain will determine whether it is in the glossopharyngeal distribution. The second part of the diagnosis is more difficult. Dr. Harris[1] has described three cases (and a suspected fourth case) of malignant disease in the throat accompanied by neuralgic pain of glossopharyngeal distribution. Weisenburg[2] described a case of tumour in the cerebello-pontine angle in which for six years there had been tic douloureux in this same distribution. In a case of glossopharyngeal neuralgia lately recorded by Fonio[4] there was an aneurysm involving the common and internal carotid arteries. It is therefore essential to exclude, as far as possible, all such source of irritation of the nerve before considering any case as one of "idiopathic" neuralgia. In the case reported here eight years have passed since the spasms of pain began, and no signs of any such exciting cause have been found, so that the neuralgia is almost certainly "idiopathic."

Treatment

In my patient, contrary to the usual experience, phenazone and gelsemium seem to have brought about a remission of the pain, and no operation has been done. When operations were first performed for this neuralgia it was thought necessary to divide, not only the glossopharyngeal nerve, but also the pharyngeal branches of the vagus, and in some cases the superior sympathetic ganglion was excised as well. It has since been found that it is sufficient to operate on the glossopharyngeal nerve alone. One case was successfully treated by Dr. Wilfred Harris by alcoholic injection. There are two operations, each of which has given complete cure in several recorded cases. The earlier one was evulsion of the nerve at the jugular foramen by operation in the neck. Subsequently, Adson[5] demonstrated on the cadaver that the glossopharyngeal nerve could be reached intracranially by an approach similar to that used for the Gasserian ganglion, and could be distinguished without difficulty and divided close to the brain stem. This operation has been carried out successfully by Dandy[6] and by Stookey.[7] No disability results from destruction of the glossopharyngeal nerve of one side. The affected side of the pharynx becomes anaesthetic, and taste is lost on the posterior third of the tongue on the same side; there is no difficulty in swallowing; the arch of the palate droops slightly at rest, but is elevated normally.

Comparison with Trigeminal Neuralgia

Glossopharyngeal neuralgia is exactly comparable to trigeminal neuralgia. The pain is of the same severity, and has the same spasmodic shock-like character. In both conditions it is excited by peripheral stimulation within the area of distribution of the affected nerve—in glossopharyngeal neuralgia chiefly by swallowing, the affected nerve being distributed to the throat; in trigeminal neuralgia by eating, talking, and washing the face, the affected nerve being distributed to the mouth and face. Long remissions of the pain may occur in both varieties. Further, the neuralgia may remain limited to, or may be preponderant in, certain branches of the nerve. In my patient it was limited at first to the tympanic branch; in other recorded cases it has been limited, or practically limited, to the main division supplying the pharynx. In trigeminal neuralgia the limitation to one division of the nerve is, of course, a usual condition.

TWO INTERESTING CASES OF PURPURA

BY

HARRY COKE, M.R.C.S., L.R.C.P.

MEDICAL UNIT, ST. MARY'S HOSPITAL

(With Special Plate)

An opportunity has recently occurred of making a careful study of several cases of idiopathic purpura, one of which was of an unusually severe type. In addition to the severity of the disease in one case, I think they are noteworthy because, as a result of the detailed examinations made, it has been possible to determine an intimate relationship between a focus of sepsis and the clinical picture. These and other cases tend to show that the term " primary or idiopathic " purpura is becoming of less and less practical significance, and that all purpuras may soon be shown to be " secondary "—that is, a symptom peculiar to some special type of infection, probably streptococcal. Very definite clinical pictures still remain, however, and, after detailing these cases, the classification of the purpuras will be briefly reconsidered in an attempt to group the cases on the more practical lines of a sound pathological basis.

DESCRIPTION OF CASES

The first case was that of a boy, aged 13, who had remained in his wet clothes for six hours in a cinema after having been thoroughly soaked by rain. The attack commenced two days later. Vomiting, diarrhoea, and colic were more prominent than the purpuric rash, which consisted only of a few spots on the ankles. These symptoms all subsided, except for a severe tonsillitis. The following week he began to have some further purpura and nausea, and he was admitted to hospital on September 24th, the temperature being 99.5° F.

Next morning severe vomiting and colic began. The vomit contained flecks of blood, and the stool showed severe melaena. The tongue was coated, and the tonsils, fauces, and the whole of the nasopharynx were covered with a thick purulent exudate of a yellow colour. The rash commenced that morning over the right scapular region, spread rapidly over the whole of the left back, and could be seen visibly progressing. It was a haemorrhage into the subcutaneous tissues, with a further rupture and haemorrhage into the deeper layers of the true dermis, particularly in the centres of the large ecchymotic patches. The area of eruption was excessively tender. The rash appeared wherever there was the slightest pressure on the skin, and was completely developed in twenty-four hours. This is well seen in the photograph of the anterior view (Fig. 1), where the purpura clearly demonstrates the sites of the clinical examination—the palpation of the spleen, of the axillary glands, the pulse at the wrist, and the pressure of the stethoscope at the apex of the heart. Ecchymoses occurred in the lower lip and the left upper eyelid, with a generalized oedema of the face. There was epistaxis, and considerable haemorrhage from the posterior pharyngeal wall. The rash was generally haemorrhagic—typical ecchymoses except over the right thorax, where there were some haemorrhagic urticarial wheals, and on the right elbow, where there were about a dozen seropurulent pemphigoid spots. At this stage the temperature dropped below normal to 97.5°, with a pulse rate of 85. The heart was not enlarged, but a soft systolic murmur was present. The spleen, liver, and glands were not enlarged.

Laboratory examination showed the following results.

Bacteriological.—From the fauces was obtained a pure, heavy growth of haemolytic streptococcus, which Dr. F. Griffith of the Ministry of Health kindly identified for us with the scarlet fever streptococcus Type IV. No other organisms were found. The bullae on the elbows were sterile. In a non-catheter specimen of the urine were a few staphylococci (albus).

Chemical.—The blood calcium amounted to 8.6 mg. per 100 c.cm. The urine was alkaline, with a faint cloud of albumin. The blood coagulation time was 2½ to 3½ minutes at 37° C.

Cytological.—Blood platelets numbered 340,000 per c.mm. Red blood corpuscles were 5,200,000 per c.mm. A differential white count showed the following percentages: polymorphs 73.5, lymphocytes 21.5, myelocytes 0.5, eosinophils 4.5.

The rash began to fade slightly on the next day, but the abdominal symptoms continued, and in the evening the temperature rose to 103°. Another blood culture was taken, but this again proved sterile. The condition rapidly settled down under intensive treatment of the tonsils and fauces, and the rash faded entirely in three days. The blood calcium was then normal at 10.4 mg. per 100 c.cm. The urinary symptoms cleared up, and the melaena gradually lessened and disappeared. Two days after the initial rise in temperature the development of a complication became obvious in the appearance of an acute otitis media in the right ear. The tympanum soon perforated, and gave rise to a profuse discharge, yielding a pure culture of haemolytic streptococci exactly similar to those isolated from the throat. This also cleared up, and the only interesting point during the convalescence was a slight lighting-up of the tonsillar infection, which immediately gave rise to another purpuric eruption on a very much smaller scale. This faded again on active antiseptic treatment of the tonsils. A faint purpuric eruption occurred on the legs when the patient sat up out of bed with his legs hanging down. This happened four times, but disappeared when he remained in bed. His tonsils were removed two months later; since then he has completely recovered, and lives a normal life with no symptoms of his former condition.

In the previous history there is no story of rheumatic fever or of "growing pains." There had been no recent contact with scarlet fever, nor had he ever had this disease. There was no history of allergy, except for an attack of urticaria which occurred after a surfeit of raspberries many years ago.

Immediately previous to the attack of purpura the patient had been under observation at a clinic pending tonsillectomy.

The second case was that of a thin, ill-nourished girl, aged 12, who had recently moved to a newly built and very damp house. On July 3rd, while she was going to bed, she noticed some spots on her legs, which were especially concentrated on her ankles. Her general health remained good until July 6th, when she was taken ill with severe headache, nausea, and continuous vomiting. Next day she was quite well again, but on the following day all the symptoms returned and continued more or less for fourteen days, accompanied by generalized purpura. During this time there was haematuria and melaena, but no pains in the limbs or joints. In the fortnight following she had two attacks while in another hospital, where she was treated unsuccessfully with haemoplastin. Her parents removed her, although she had still some purpuric spots and considerable haematuria. Every time she got out of bed the purpura increased. Another abdominal attack took place, and she was admitted to St. Mary's Hospital on September 2nd. On admission the patient was vomiting continually, with marked intestinal colic, a rapid pulse, but no pyrexia. There was a generalized purpuric rash of small petechiae concentrated on the ankles and wrists. The abdominal symptoms rapidly cleared up, and the rash faded in three or four days. There remained, however, severe haematuria and melaena. The urine analysis showed a moderate cloud of albumin, large quantities of blood, calcium oxalate crystals, hyaline, granular and epithelial casts. After the subsidence of the acute symptoms the melaena and haematuria stopped.

The interest of this case lies in the search for a cause. The tonsils were small, and a culture showed no pathological flora. The teeth were all good. Duodenal drainage through a Ryle's tube revealed no biliary infection. A catheter specimen of urine was sterile. The stool showed three pathological organisms—two types of streptococcus (*viridans* and *haemolyticus*) and a coliform bacillus giving the reactions of *B. asiaticus*. These were the only definite infections demonstrable, and a vaccine was prepared from them. For five weeks the girl remained in hospital in a stationary condition. During this time she had no attacks, her only symptom being some slight occult blood in the urine. She was given an injection of vaccine containing one-third of a million of each type of bacteria. She did not feel well for three days after it, being languid, with slight headache and loss of appetite. On the fourth day a purpuric rash appeared on

the legs and arms, the nephritis recurred, and, in fact, all symptoms returned except the abdominal, which were represented only by the reappearance of a considerable melaena. This minor attack having subsided, she was given a course of therapeutic vaccination, starting with a dose of 55,000 of each type once every five days, each dose being increased by 25,000. No further symptoms occurred, and she was discharged at the end of the year with only one latent but serious complication—namely, a considerable degree of subacute nephritis. She has a very poor water excretion, and the range of urea concentration (Calvert) is only 0.9 per cent. She is, however, perfectly fit in every other way, and is getting about as a fairly normal child.

DISCUSSION

There are several interesting points in these two cases. In the first there is the spectacular rash, and the direct relationship between the infection of the fauces and the general symptoms. These facts show that there was a gross toxaemia affecting the endothelial linings of the capillary walls, which apparently allowed a mechanical "micro-trauma" to cause the rupture of the vessels. The endothelial injury appears to have lasted for some time, as shown by the reappearance of the purpura each time the legs were hung out of bed. There was then an increased venous congestion, which necessitated increased capillary pressure. Further, the fact of the lowering of the calcium content in the blood in association with the profuse purpura is noteworthy, while the platelet count was never abnormal. The general appearance of the patient was never that of one in a severe toxic state, and the temperature did not rise until three days after the appearance of the rash, when it could easily be accounted for at that time by the development of otitis media. Again, one would have expected on admission a hectic temperature with a pronounced cervical adenitis in association with the very septic condition of the pharynx. Perhaps this lack of glandular localization explains the easy passage of the toxins into the blood stream, thereby causing a general toxicosis of the vessel walls. The appearance of urticarial and pemphigoid spots is atypical of the condition described by von Henoch, and, in fact, never occurred in his cases, but is mentioned in several of those of the arthritic Schönlein type; it is generally recognized as occurring in many cases nowadays, and is even placed by Osler[1] in a separate group designated purpura urticans.

In the second case we have the complete absence of joint symptoms and the presence of the common complication, nephritis. One must note in this case also the relation between the toxins of the haemolytic streptococcus and the effect produced by an overdose of these toxins. The attack produced artificially by the overdose of vaccine might be explained as being similar to the experiments of Glanzmann,[2] who injected a foreign protein with the same results; but, in view of the fact that the protein was provided by the patient herself, it must show either that it is analogous to the autogenous protein shock by the injection of whole blood, or that the toxins of the specific haemolytic streptococcus, as such, are the irritative protein. A cure cannot be claimed in the second case, since it is usual for such cases to end spontaneously, but it may be pointed out that if the disease was not in fact terminated by the vaccine treatment, the end at any rate coincided with such treatment in a patient who had, a few days before, shown an active haemorrhagic diathesis. The complete absence of any arthritic symptoms dissociates this case from those of the true von Henoch type, and it should come under the abdominal type in the classification below, no better name for which has yet been provided than merely "atypical," as suggested by von Henoch himself some sixty years ago.

CLASSIFICATION OF PURPURA

With regard to the classification of purpura, the first point, which seems fairly clear, is that the standard textbooks of to-day give no satisfactory or unanimous opinion on the subject. It appears also that with a very little "give and take" a useful and concise grouping could be arranged. Owing to the present muddle of types and terminology it is necessary, if one intends to keep the old names associated, to go back to the original descriptions and to adopt the views of their authors, which were remarkably stable, even if incorrect. By incorporating recent pathological knowledge into those descriptions we can frame a modern classification.

Primary or idiopathic purpura has been discussed as a clinical entity since the year 1713,[3] and authors have described a similar type as von Henoch's purpura, or as Schönlein's purpura, some mentioning one name, some both; a few attach neither name. It is with the types identified with the names of von Henoch and Schönlein that I wish to deal particularly.

Purpura with abdominal symptoms was discussed by von Henoch in 1874,[4] he being the first to separate that type from the other forms. But even he, as we learn from his paper, thought that his cases were only complicated forms of the Schönlein "peliosis rheumatica." Von Henoch originally described the characteristics of the group as being "a combination of purpura with the abdominal symptoms of colic, tenderness of the abdomen, vomiting, and melaena, and often associated with atypical rheumatic pains in the limbs and joints." He stood almost alone in his views concerning Schönlein's disease, for the general opinion of his contemporaries on the subject of "peliosis rheumatica" is aptly summed up in the words of von Dusch and Hoche,[5] that no one really seriously considered that this purpura arthritica was a manifestation of rheumatism proper, but that the name was held "in deference to the memory of a great clinician." Let us to-day, therefore, also honour the name, and designate the arthritic form of purpura as that of Schönlein's; but let us be equally emphatic in the attempt to erase the term "peliosis rheumatica" from our minds. Schönlein's opinions are handed down to posterity through his students, mainly von Traube, and consequently a large variation from the original conception has ensued. It was von Henoch himself who held longest to the view that his purpura was merely a complicated form of the arthritic type, and he never agreed in his writings that it had anything to do with rheumatism. In later years in Germany the term peliosis rheumatica was entirely dropped, and the term Henoch's purpura was regarded as including any case of idiopathic purpura with abdominal symptoms, with or without arthritic manifestations.

The most suitable classification seems to me to be a combination of the terminology of de Krauss[6] and Biedert-Vogel,[7] while keeping in view our modern idea that all idiopathic purpura is probably secondary to some septic focus of infection. In fact, a classification of clinical pictures results, the features of which are merely a reaction to some specific type of toxin, just as the scarlatiniform rash is a typical reaction to the specific toxin of the streptococcus of scarlet fever.

Two groups emerge, the first containing purpura simplex and purpura haemorrhagica, and the second the complicated forms of purpura—that is to say, purpura with abdominal symptoms, or with arthritic symptoms, or with both. Let us first dismiss several uncontroversial groups. The clinical picture of purpura simplex all are agreed upon. The modern tendency is to separate this as an essential thrombocytopenia purpura, and it seems to include, as its more severe form, that which was formerly known as "morbus maculosus" of Werlhof, or

synonymously purpura haemorrhagica. The pathology of this thrombocytopenia is rapidly becoming established, but as to the primary cause of the diminution in the platelets we are still ignorant. Despite the great strides made in haematology by Piney[8] and others, we are still left on the horns of the thrombocytopenia dilemma by having to decide between the very opposite views of (1) Kaznelson,[9] who thinks that it is a hyperdestruction of platelets, and (2) Frank,[10] who considers that it is a fundamental defect in their production. This diminution occurs certainly as the only demonstrable change in many cases of purpura haemorrhagica, but it cannot as yet be universally accepted. In addition, many other cases of secondary purpura show a lack of platelets, as in two of our recent cases, one of aleukia haemorrhagica with a platelet count of 34,000 per c.mm., and the other a lymphosarcoma with a count of 72,000 platelets per c.mm. From the two cases of purpura outlined above we may have to take more consideration of the calcium metabolism.

Purpura is a symptom in a multitude of diseases, as outlined by most authors to-day. The second group which I have mentioned above must be a small one, but none the less important, among the infective or toxaemic groups of all the secondary purpuras. The occurrence of purpura in severe cases of rheumatic fever cannot be denied, but this form is sufficiently far removed from the picture of Schönlein's arthritic purpura to avoid confusion. The purpura of rheumatism usually occurs as a generalized rash in a patient who is extremely ill, severely toxic, with very marked rheumatic symptoms and signs, such as severe heart lesions, nodules, and pyrexia; it does not appear in mild cases. In Schönlein's disease, however, there is a repetition of mild attacks, the eruption occurring solely on the arms and legs, with mild joint pains, and only occasional swellings. The general picture of Schönlein's purpura is thus only that of a mild, though repeated, transient infection, with usually a moderate follicular tonsillitis as the most aggravating symptom. The German authorities gave up the association between true rheumatism and Schönlein's purpura some years before the English did, and we must be equally emphatic in dissociating them, especially in view of our modern conception of the various toxicoses in relation to arthritis.

The final point to be considered is how soon it will be possible to abandon the terms " primary and idiopathic " and " secondary," by considering all purpura to be a symptom of a special infection, the specificity of the infection being perhaps combined with an unknown deficiency of a vitamin nature, affecting calcium metabolism, which would lead us to consider the parathyroid.

In the groups appended below we satisfy ourselves, and do not offend the memory of any of the old order.

Group I.—" Thrombocytopenic Group."

1. Purpura simplex.
2. Purpura haemorrhagica, or morbus maculosus of Werlhof.

Group. II.—" Toxaemic Group."

1. Purpura with abdominal symptoms.
2. Purpura with arthritic symptoms, or Schönlein's purpura.
3. Purpura with abdominal and arthritic symptoms, or von Henoch's purpura.

I wish to thank Professor Langmead for his permission to publish these cases, and for assisting in correlating the evidence; Dr. Leonard Colebrook and Dr. F. Griffith for their bacteriological work; and also Dr. Hurst Brown, of the Medical Unit, for the chemical pathology.

MYCOSIS FUNGOIDES FOLLOWING LAPAROTOMY

BY

R. OWEN-JONES, M.B., B.S., F.R.C.S.ED.

ST. LUKE'S HOSPITAL, CHELSEA

(With Special Plate)

The rarity of the following complication of a laparotomy for perforated duodenal ulcer merits publication.

A builder's labourer, aged 44, was admitted to St. Luke's Hospital, Chelsea, with a history of having been seized with acute epigastric pain and nausea whilst at work five hours before. He drank some brandy and a pint of ale, with the object, presumably, of relieving the pain. The history of epigastric pain over a long period, and his condition on admission, led to the diagnosis of an acute perforation.

A mid-line supra-umbilical laparotomy was performed under chloroform-ether anaesthesia as soon as was possible. On opening the peritoneum the usual escape of free gas and opalescent flaky fluid occurred. No specific odour was detected. A small perforated ulcer was discovered on the anterior surface of the duodenal side of the pyloric vein. This was dealt with by a single purse-string suture and by an omental graft. The peritoneal cavity was drained suprapubically and through a low stab wound far back in the right loin.

With the exception of some hypostatic lung congestion, the patient progressed satisfactorily for a week, when there appeared to be an area of commencing cellulitis around the loin stab wound. This gradually spread forward towards the ventral surface of the abdominal wall. The wound was still discharging some serous fluid and the indurated inflammatory area was treated as a parietal inflammatory complication. After a few days the superficial skin layer became a sloughing covering to a plane of pus in and on the deeper layer and subcutaneous tissues. Nerve endings were exposed, analgesics had to be given often, and Carrel-Dakin irrigation was instituted. In spite of this the infected area spread forward towards the mid-ventral line, up to the costal margin, and down as far as the right iliac crest. Anti-streptococcal serum and anti-*Bacillus welchii* serum were exhibited without improvement; 1 in 1,000 flavine was substituted for the hyperchlorite, and hot fomentations were continued. The Wassermann test was negative. Examination of a swab of the discharge under the advancing edge showed streptococci, *Staphylococcus aureus*, and diphtheroid bacilli. An autogenous vaccine was given in increasing doses.

The patient's general condition became steadily worse, morphine in various forms, and other analgesics being necessary. He had no recurrence of the gastric symptoms, the drainage wound closed, and the laparotomy incision healed normally. The infection of his parietes, however, spread apace. It had the appearance of an extensive superficial carbunculosis; the advancing edge showed a marked serpiginous outline, the result of multiple crescentic inroads into indurated skin, which had a definite ragged overhanging edge. This appearance led us to make another Wassermann test, which again proved to be negative. At the costal margin and iliac crest the infection advanced no further, and from

the loin wound forward it healed over gradually and was weakly epithelialized, whereas towards the mid-line it progressed steadily. Within two inches of the incisional scar it converged to a point and then tunnelled the tissues below the scar, leaving it untouched, to a position about three inches from its left border and then diverged again, to produce a similar extensive lesion from the costal margin to iliac crest on the left side of the abdominal wall. Various solutions and dressings—hydrogen peroxide, oxycyanide of mercury 1 in 10,000, sanitas, and salines, with glycerin ichthyol to the edges—were applied in vain. Another swab examination showed pyogenic organisms only. A urinary examination showed *B. coli* and *Streptococcus faecalis* in culture. Intravenous mercurochrome and oral iodides were ineffective. On reaching the mid-axillary line on the left side, the lesion again converged to a tunnel 3/4 inch wide and about 4 inches long to fan outwards again on the dorsal surface, whilst healing slowly took place on the abdominal wall. The continued use of sedatives, the pain, and the toxic absorption reduced the patient's condition to one of danger. The affected area at this stage (six months after the operation) formed a striking picture, of which the following were outstanding: the greenish-black extensive sloughs with foul pus exuding beneath their edges; the pink newly epithelialized healed area, with branching new arterioles spreading weblike across it; the immune island of healthy skin around the mid-line incisional scar; the narrow communication channels across the mid-line and in the left loin; the multiple crescentic edges; and the inflamed heaped-up attacked tissue around. The odour in the vicinity of the man's bed was almost unbearable, and large quantities of deodorants had to be used. The advancing edge eventually reached to two inches from the other side of the vertebral column, to the level of the fourth dorsal vertebra above, and to the iliac crest below.

Microscopical examination of a wedge section of the edge, removed under gas, showed numerous organisms superimposed on a growth of mycosis fungoides.

The report of Dr. L. M. Hawksley of the pathological staff of the Cancer Hospital was as follows:

"The microscopical appearances are those of a granulomatous condition with superficial and deep destruction of tissue. The dermis is extensively infiltrated with a growth of polymorphic connective tissue cells with ill-defined margins, many showing mitoses, some being multinucleated, and others resembling plasma cells. The masses of cells show a tendency to arrangement in strands, and in more superficial parts of the corium, islets of down-growing epithelium have been snared off by them. The whole of the tissue is very oedematous; fibrous tissue appears as small fragments; sebaceous glands, hair follicles, and sweat glands are not seen. Some of the epithelial cells show vacuolation; where not destroyed by ulceration the epithelium is considerably thinned. In the area of more normal skin, granular particles of irregular shape can be detected in the connective tissue cells. Gram-stained films show massive invasion of the greater part of the tissue with long-chained streptococci (in the ulcerated part numerous other organisms also). The microscopical features of the tissue correspond with those of 'granuloma fungoides.'"

The patient died ten months after admission.

The photographs (Special Plate, Figs. 1 and 2) show the abdominal part of the lesion; the patient was so ill that none could be taken of the affected area on the back. Apart from the rarity of the infection, the interesting features of the case are the mode of infection possibly from the perforation of the duodenum through the drainage wound to the abdominal parietes, and the complete immunity of the laparotomy scar to the infection. We are forced to consider whether the infection occurred from the ale which the unfortunate man took to relieve the pain of the perforation, or from a premycotic nidus in the abdominal wall.

I desire to thank Dr. Hawksley for the great help she gave in the case, and to the medical superintendent of St. Luke's Hospital for permission to publish the case.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

CUTANEOUS INFECTION WITH A DIPHTHEROID BACILLUS*

Diphtheroid bacilli are commonly found vegetating upon the surface of the human skin, and upon the lining membranes of the various body cavities. The group as a whole is singularly devoid of pathogenic properties (Hewlett†). The following case is of interest for two reasons: first, because it appears to be a true case of cutaneous infection with a diphtheroid bacillus; and, secondly, because the organism implicated was identical with the Klebs-Loeffler bacillus in every respect save toxin production.

A married Jewish lady, aged 55, with a family of four children, had never had diphtheria, nor had any of the members of her family; so far as she was aware, none of them had been in contact with any case of diphtheria prior to the appearance of her lesion. Towards the end of August, 1927 (the patient was rather vague as to the exact date), she noticed a small papule on the upper and outer aspect of her right thigh. This papule was quite painful to the touch, but it did not "throb," and there was no visible inflammatory zone. It rapidly enlarged to approximately the size of a lentil. The patient was very definite in her description of the sharp pain occasioned by merely pressing lightly upon the papule. After a few days the papule developed into a pustule, which ruptured spontaneously and exuded a thin, watery, deep-yellow fluid.

The patient paid little attention to the lesion at first, ascribing its formation to the friction of a badly fitting pair of stays; she was very stout, of short stature, and in the sitting position the bones of her corset pressed deeply into the flesh of her thighs. The lesion slowly developed into an irregular, shallow ulcer, and eventually, towards the end of September, the patient came to Queen's Hospital for treatment, mainly because she was "afraid that it was a cancer."

She was found to have an irregular linear ulcer on the upper and outer aspect of the right thigh. It measured 1½ inches in length by 1/2 inch in breadth, and its long diameter was inclined almost at right angles to the long axis of the thigh when she assumed the prone position. The ulcer was shallow, with rolled edges and a smooth, purplish-red floor, from which a thin, deep-yellow, sero-purulent fluid was exuded profusely. The lesion was quite sharply demarcated from the surrounding skin, and there was no encircling zone of erythema or any appreciable induration. The ulcer was not painful on palpation. At each end of the ulcer there was a pocket in the skin; at the lower end the pocket was very small, admitting only a small probe; but at the upper end the pocket was much larger, extending for about 1/2 inch into the skin. From this pocket a deep-yellow, sero-purulent fluid could be easily expressed in relatively large amounts by gentle pressure.

Film preparations of this discharge, stained by Gram's method, showed large numbers of slender, Gram-positive bacilli, together with a moderate number of polymorphonuclear leucocytes. Preparations stained by Neisser's method showed bacilli with the typical morphological appearance of the Klebs-Loeffler bacillus. No other organisms were seen in these first film preparations, though later on, after the lesion had been dressed for some days, numbers of the ordinary skin staphylococci made their appearance. Cultures on hormone blood agar and on Loeffler's serum medium yielded luxuriant, pure cultures of this bacillus. The microscopical appearance of the organism from the cultures was identical with that of the Klebs-Loeffler bacillus, the granules being particularly large and abundant.

Agglutination of the organism against the patient's serum failed to show the presence of any agglutinins. The organism was non-virulent for guinea-pigs, three separate tests being

† Hewlett, R. T.: *A System of Bacteriology*, Medical Research Council, 1930, vol. v, p. 135.

performed: (1) with the discharge from the ulcer.; (2) with an emulsion of the primary culture on Loeffler's medium; and (3) with the fourth transplant on Loeffler's medium, about one month after the isolation of the organism. Several attempts to demonstrate toxin production in shallow cultures of various liquid media were unsuccessful. The organism grew in the form of a fine pellicle on veal broth, and produced acid in serum water containing 1 per cent. of glucose; no appreciable acid production occurred in a 1 per cent. saccharose serum water medium. Cultures on Loeffler's medium grew rapidly and luxuriantly, and produced a deep golden-yellow pigment. The organism has now been under observation in artificial culture for three years, and pigment production still occurs, though it is not so intense now as it was immediately after isolation. The bacillus still shows the typical morphological appearance of the true diphtheria bacillus when stained by Neisser's method, and the culture has been regularly used for teaching purposes in preference to the laboratory stock culture of the Klebs-Loeffler bacillus, because of its more profuse formation of "polar" granules. Cultures taken from the tonsils, nasal passages, and vagina of the patient did not yield any growth of a diphtheroid bacillus resembling this organism. Hoffmann's bacillus was present in the tonsillar cultures. The patient gave a positive Schick reaction.

The lesion showed no inclination to heal under the application of various mild antiseptic dressings, and eventually Mr. H. Donovan, assistant surgeon to Queen's Hospital, was obliged to open up the two pockets and scrape them thoroughly. This treatment, together with iodoform dressings, produced a rapid improvement, and the patient was discharged from attendance at the out-patient department three weeks later. When seen eight weeks afterwards the lesion had healed completely, and, in answer to a personal inquiry, the patient reported by letter, in January, 1928, that there had been no recurrence.

ACUTE ALCOHOLIC POISONING DUE TO THE APPLICATION OF SURGICAL SPIRIT TO THE LEGS

A boy, aged 8 years, was seen by me on January 7th, and examined before undergoing an operation for removal of congenitally enlarged semimembranosus bursae on both legs, which was to be performed on January 9th. He was then quite well and the urine contained no sugar and no albumin. The legs were prepared for the operation on January 8th. They were both shaved and washed with ether soap from the groin to the ankle. They were then covered from the groin to the ankle with a towel wrung out in surgical spirit, over which a dry towel was placed and kept in position by three rubber bands. This first dressing was applied at 12 noon, and it was repeated at 4 p.m. and 8 p.m. At 9 p.m. the boy appeared normal. At 11 p.m. he was seen by his mother and was thought to be asleep, and seemed to be normal. At 12.30 a.m. on January 9th his mother, who was sleeping in the same room, was aroused by hearing him vomit. He brought up food, but did not speak at all, and his mother thought he was still asleep. He continued vomiting and retching on and off during the night, but did not wake up. When seen by the nurse first thing in the morning he was unconscious, the pulse rate being 160. The respiration was regular—24—and the temperature was normal. I was called to see him at 8.30 a.m., and on examining the vomit noticed that it had a smell of spirit. The boy was unconscious, pale, and warm, the pupils were small, reacted to strong light, and there was slight internal strabismus of the right eye. The corneal reflex was absent. The limbs were flaccid, the plantar responses flexor. There was no sweating. From 9 a.m. the unconsciousness became less deep, the corneal reflex returned, and the reflexes became more brisk. Nystagmus was present. At 1 p.m. I saw him again in consultation with Dr. G. E. Beaumont; the patient was then beginning to recover consciousness, but still vomited up small quantities of turbid brown fluid. He could move all his limbs and, when asked, complained of frontal headache and of feeling sick. Speech was slurring but coherent. The pupils were of medium size and reacted to light; the knee-jerks were present, and the plantar responses were brisk and flexor. The abdominal reflex was sluggish. The pulse rate was now 142, the respirations 20, and the temperature 98° F. His bowels had opened involuntarily once in the morning, and it was not possible to obtain a specimen of urine then. The vomit was sent to Professor E. C. Dodds at the Middlesex Hospital, and he reported that alcohol was present. A specimen of urine which was obtained at 5 p.m. was also sent to him, and this contained alcohol as well.

In view of the boy's possible idiosyncrasy to ether, Sir Francis Shipway gave him a small trial injection of avertin. This led to no toxic symptoms, and the operation was performed a week later without untoward incident, Sir Francis Shipway giving an avertin-gas-oxygen anaesthesia.

Mr. Trethowan, who operated, tells me that the skin preparation was done according to a routine method, and that this is the first patient who has shown symptoms of any alcoholic absorption.

Reports of Societies

ALKALIS IN RENAL COMPLICATIONS OF PREGNANCY

At a meeting of the Obstetrical and Gynaecological Section of the Royal Society of Medicine, held on February 20th, with the president, Sir EWEN MACLEAN, in the chair, Dr. A. ARNOLD OSMAN read a paper prepared jointly with Dr. HAROLD G. CLOSE, on observations on the plasma bicarbonate and the value of alkalis in the treatment of some of the renal complications of pregnancy. The work was carried out in the department for medical investigations, Queen Mary's Hospital, E. Observations on cases of normal pregnancy showed that there was a considerable decrease in the plasma bicarbonate, and that it remained at about the same low level throughout the period of gestation. The water content of the blood and tissues was increased in pregnancy, and was greatest in those with the lowest plasma bicarbonate. Alkali therapy was carried out in albuminuria of pregnancy, in pre-eclampsia, and in cases treated prophylactically. Severely affected patients were kept in bed, and all were given a full diet, including meat. The intake of fluid was limited. No purgation was allowed. The treatment consisted solely of equal parts of potassium citrate and sodium bicarbonate by the mouth, 50 grains of each to an ounce and a half of water, as many times a day as was found to be necessary to produce a satisfactory diuresis. Usually 150 grains a day were given, increased by 100 grains until the desired result was obtained. The dose was regulated by the volume and reaction of urine passed. The results showed a decrease in albumin and clearing up of the oedema. Increase in dosage at the beginning might mean an increase in the oedema, but this subsided when the dose

was further raised. There was no danger of the occurrence of alkalosis or tetany. Alkali therapy diminished the severity of pregnancy toxaemias, but could not be relied upon to prevent the onset of some of the graver symptoms in all cases. The authors asserted that alkali therapy had its uses in the treatment of the types of cases above mentioned; it promoted diuresis, and diminished or controlled oedema and albuminuria. The discomfort of sweating, purgation, and extreme limitation of the diet was avoided. The graver symptoms might not be prevented by alkali therapy alone in all cases, but they were diminished in severity. The results were promising, and justified further work on the subject.

Mr. G. F. GIBBERD regarded the recurrence rate of less than 20 per cent. in prophylactic treatment as strong evidence that alkali treatment was of real value. The usual recurrence rate was not lower than 30 per cent., and probably was as high as 50 per cent. He was of the opinion that the results of the usual methods of treatment would be improved if the administration of alkalis were also adopted. Dr. OXLEY expressed the view that albuminuria was of two types—one postural and one toxaemic. He believed that if strict eliminative treatment were carried out eclampsia could be prevented. A vegetable diet was of value in the case of those who had suffered from albuminuria, and by this means the depressing effect of continued alkali treatment could be avoided.

ECZEMA OF INTERNAL ORIGIN

At the meeting of the Section of Dermatology of the Royal Society of Medicine on March 19th, with Dr. ERNEST DORE in the chair, Dr. G. H. ORIEL read a paper on the pathogenesis of eczema of internal origin, and other allergic diseases.

The paper reported the results of a preliminary investigation conducted at the asthma and dermatological clinics, Guy's Hospital. Several cases were shown; one in particular was that of a lad, aged 19, who had suffered from eczema all his life, and whose father was similarly affected. He was sensitive to egg, fish, wheat, and other foods; the mere rubbing into his skin of a minute quantity of egg albumen caused a marked urticarial reaction, though he was now much less sensitive in this respect than formerly. When first seen he had also severe asthma. Dr. Oriel said that it had been shown that the specific antigenic substance of such a food as egg actually circulated in the body. If the serum of an egg-sensitive person was injected intradermally into a normal person's skin, and this normal person had a meal of egg twenty-four hours later, a wheal appeared at the injection site in a certain number of cases; it had been shown by other workers that this was more likely to occur if the injected person had either achlorhydria or hypochlorhydria. When this test was positive, the antigenic substance must travel by means of the circulation. How was it eliminated? It might be destroyed by ferments or eliminated by the kidneys or intestines. In the urine in these cases Dr. Oriel had isolated a substance, containing nitrogen, and appearing to be a protein, with a carbohydrate group attached. It was soluble in dilute alkalis. When injected intradermally into a sensitized person, a reaction followed similar to that seen on the injection of an antigen. Treatment therefore appeared hopeful, since it should be possible to desensitize the patient to this material. He had also tried to show that a specific antigen, such as that of milk, could be identified in the urinary proteose of a milk-sensitive patient, and this was the case. It seemed clear that the urinary proteose in sensitization contained the antigen to which the patient was sensitized. The phenomenon did not take place when the serum of a normal person was injected into a guinea-pig, but passive sensitization to urinary antigen had been found in asthma, urticaria, migraine, eczema, and rheumatoid arthritis. It did not necessarily follow that eczema of internal origin was eczema of alimentary origin. It was quite possible that in eczema the skin became sensitized to the products of bacterial action on body tissues, and it was probable that focal sepsis might cause body tissues to act as a foreign protein. In these cases the removal of the focal sepsis would cut off the supply of antigen, and this would relieve the eczema. With regard to the boy mentioned, who had been treated by desensitization with his urinary proteose, the patient had been under treatment for eighteen months, and whereas his asthma had formerly been continuous, it had not troubled him for twelve months, and his skin also had been greatly improved, though at first the injections—which were given weekly—caused a marked exacerbation both of his asthma and of his skin condition. Dr. Oriel mentioned that more than 200 patients had now been treated.

Dr. H. W. BARBER said that he had been watching this research throughout, and every test had been made to reveal fallacies. As a result he had no doubt whatever of the accuracy of Dr. Oriel's work and of the deductions made from it. In these sensitized cases it was not, as a rule, a question of a person being sensitized to a primary antigen, but rather of sensitization to a secondary antigen, produced by the action of primary antigens on the tissues. He had found the treatment remarkably good in dermatitis herpetiformis, and in rheumatoid arthritis associated with psoriasis, yet in uncomplicated psoriasis it gave no good result. Great care was necessary in dosage; a slight excess might cause a serious flare-up in the joints in rheumatoid arthritis cases.

Dr. G. B. DOWLING said that it was well known that the antigen responsible for a generalized eczema was often derived from the skin, and in such cases the ether reaction was always well marked. It was evident, therefore, that this tissue antigen, or something closely allied to it, might be present in the urine. If such an antigen could be isolated and used for desensitization, it should do as well as any other antigen, as it was well known that the sensitivity of tissues sensitized to a number of proteins could be removed by the application of any one of them. Dr. Oriel had taken charge of four of the speaker's cases of dermatitis herpetiformis, and treated them by injections of proteose, without using arsenic. All the cases had shown very marked amelioration, and one of them had cleared up completely.

Dr. H. C. SEMON had had three cases of the pruriginous eczematous type, and all had improved. Dr. A. WHITFIELD asked if there was any quick clinical test. He had concluded from the original paper by Barber and Oriel that by simply testing the urine, acidifying it with strong sulphuric acid, adding ether, and shaking, a marked difference would be apparent between the proteose-containing urine and normal. Yet he had done it in cases of dermatitis herpetiformis, urticaria, asthma, and prurigo associated with hay fever, and all showed some amount of syrupiness in the ether.

Dr. BARBER, replying to some questions, said that in his opinion the ether reaction as a clinical test was useless, because a large number of people who were apparently normal gave a good ether reaction. In a robust and very fit person, however, the reaction was quite small. It was largely a question of degree, and for that reason he had abandoned it as a test. The really important matter was the amount of proteose secreted during

twenty-four hours. In a patient with recurrent urticaria the proteose excreted during quiescence would be found to be very much less than the amount excreted during an actual attack, and the proteose during an attack was much more antigenic than was that produced in the quiescent interval.

PERFORATION OF JEJUNAL ULCER

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland held on March 6th, with the president, Mr. R. ATKINSON STONEY, in the chair, Mr. F. J. MORRIN read a paper on spontaneous perforation of jejunal ulcers, and reported three cases in which no evidence of any specific cause was forthcoming, and which had accordingly to be included in the class of simple intestinal ulcers. The first patient was a male, aged 65, with a history of abdominal discomfort for six months, who perforated suddenly; operation disclosed a perforation of the jejunum eighteen inches from the duodeno-jejunal flexure; this patient succumbed. The second patient was a female, aged 39; the perforation was not found at operation, but, later, necropsy disclosed a pin-point perforation of the jejunum, two feet from the flexure. The third patient was a female, aged 47; operation revealed perforation of an inflammatory area in the terminal jejunum; this patient recovered. From a survey of eighty-one reported cases, it appeared that two types of case were met with. In one, the ulcer progressed rapidly to perforation, and was first seen as an acute abdominal catastrophe. In the other a chronic ulcer produced indefinite gastro-intestinal symptoms for a variable time before perforating. The etiology of the condition was obscure, but it might perhaps be ascribed to the localization of circulating toxins or bacteria in association with degenerative arterial changes in the intestinal wall. The condition was more common in males, more common in the ileum than in the jejunum, and the pathological appearances resembled those met with in duodenal and gastric perforations. The resulting peritonitis was most grave, the mortality being about 66.7 per cent. On account of its rarity many cases had been overlooked at operation, and while the peritonitis of perforation did not impose an exact preoperative diagnosis on the surgeon in every case, it was important to remember the possibility of a perforation of the small intestine when examination of the appendix and stomach was negative.

The PRESIDENT, referring to diagnostic signs in cases of perforation, said that he thought a point of considerable importance was the occurrence of the chief pain and tenderness in the left iliac fossa. He had never come across a case of perforation of the small intestine. Mr. T. J. LANE spoke of a patient with perforated gastro-jejunal ulcer, and said that the tenderness in this case was on the left side. Mr. H. STOKES referred to a case of peptic ulcer of the appendix, in which the history was exactly similar to that of gastric ulcer.

SPINOCAIN ANAESTHESIA

Dr. R. W. SHAW, in a paper on spinocain, said that this substance, though not a perfect spinal anaesthetic, was the best he had yet used. The spinocain solution, being lighter than the spinal fluid, floated on the latter like the bubble in a spirit-level. Height of anaesthesia was controlled by the degree of Trendelenburg position employed, and by the amount of mechanical dissemination effected by mixing the spinocain with the cerebro-spinal fluid in a 10 c.cm. syringe. The patient was anaesthetized lying on the side. Preliminary injection of ephedrine-novocain solution was made over the site selected, thus anaesthetizing the skin and interspinous ligament, the ephedrine maintaining the blood pressure. Anaesthesia was usually complete in five to ten minutes, and there was a marked absence of shock in most cases. The speaker had used the anaesthetic in forty-two cases. Operations were varied in kind, and included ten abdominal cases. The results were satisfactory, only three failures being experienced. There were also two cases in which, the operation being long, some general anaesthetic was administered at the close.

Mr. W. PEARSON referred to two cases in which Dr. Shaw had given spinocain for him, and in which it had been most successful. He thought it was a good anaesthetic, and that it marked a great advance on previous solutions, but he did not regard it as infallible. Mr. A. B. CLERY mentioned a case in which it had been necessary to use three ampoules before anaesthesia was complete. On several occasions he had found that any traction on the peritoneum produced pain.

Mr. F. J. MORRIN said that he had been using spinal anaesthesia for ten years, and its advantages were immense. By its use it was possible to get an extraordinary amount of abdominal relaxation, and no anaesthetic was so successful for prostate operations. Its chief disadvantage was the marked fall in blood pressure which was apt to occur. In his experience spinocain was not so satisfactory as novocain. He had recently been using percaine, and thought this drug was the most successful. In some cases headache was very severe, and he had found the injection of 10 to 15 c.cm. of hypertonic saline very useful in alleviating this symptom.

Dr. SHAW, in reply, said that he thought the fall in blood pressure was avoided when spinocain was used; it had not caused him any anxiety. He had not found that patients complained very much of headache, but in one case he had to give an injection of hypertonic saline.

GYNAECOLOGICAL TUMOURS

At the last meeting of the North of England Obstetrical and Gynaecological Society, held at Sheffield, Professor MILES PHILLIPS (Sheffield) showed a specimen of perforating adenoma of the cervix. The specimen was removed, together with the normal appendages, by an extensive panhysterectomy on a provisional diagnosis of perforating endometrioma of the recto-vaginal space. The patient was 45 years of age, with a history of persistent backache for nine years. The point of interest in the specimen lay in a fistulous track leading from the cervical canal close to the internal os to a point high up in the posterior fornix. The vaginal opening contained a small red nodule. This nodule and the lining of the fistula consisted of glandular tissue, cervical in type, and covered by columnar epithelium. In some areas, and especially in the nodule, the glands were surrounded by a cystogenous mantle similar to that found in endometriomata. The nodule appeared by its well-marked stroma and greater vascularity to be the apex of the growth.

Professor W. FLETCHER SHAW (Manchester) showed an epithelioma of the vulva removed from a woman of 23 years. The patient had complained of local irritation for two years, an ulcer had been noticed for six months, and there had been a foul discharge for three months. The growth extended from one inch below the clitoris to a quarter of an inch above the anus, involving the right labium majus and minus and the posterior inch of the left labium majus. The right inguinal glands were extensively involved. The Wassermann reaction was negative, and section of the growth showed epithelioma. In spite of extensive removal of the growth and glands, followed by deep *x*-ray therapy, the patient died fourteen

months later, a mass being present in the pelvis. Professor Shaw gave a short account of similar cases which had been recorded.

Mr. N. L. EDWARDS (Derby) demonstrated two specimens. The first was a uterus containing a sarcomatous polypus. A fibroid polypus showing sarcomatous degeneration had been removed a year previously from the same patient, who had at the time refused hysterectomy. The second was a uterus and appendages with a left-sided fimbrial cyst with twisted pedicle and early papilliferous carcinoma of the right ovary.

Professor D. DOUGAL (Manchester) described a case of pseudo-myxoma of the ovaries and peritoneum, referring to two other cases he had previously reported, and giving a brief survey of the literature. In the case at present reported there was no cystic enlargement of the appendix, though a considerable quantity of pseudo-mucin was adherent to it and the caecum. Both ovaries showed large pseudo-mucinous cysts; that on the left side was evidently leaking into the abdomen. The omentum was converted into a cake-like mass, containing many small spaces filled with pseudo-myxomatous material. Both cysts were removed along with the uterus. It was not considered advisable to isolate and remove the appendix. In Professor Dougal's two previous cases the appendix was enlarged and distended with myxomatous material.

Miss RUTH NICHOLSON (Liverpool) described a case of double pyosalpinx in a girl of 16. The patient had been treated for a vaginal discharge at the age of 5. The periods had started at 14, and had been more or less normal. When seen she had a temperature of 103° with a rapid pulse. This continued for fourteen days, when the abdomen was opened and a double pyosalpinx and small uterus were removed. The pyrexia subsided on the third day and the patient made a good recovery. Miss Nicholson was confident in excluding the possibility of a reinfection.

TRANSPLANTABLE TUMOURS

At a meeting of the Liverpool Medical Institution, held on February 12th, with the president, Professor W. BLAIR BELL, in the chair, Dr. M. DATNOW read a paper on a malignant transplantable tumour of the rabbit. The speaker outlined the work of Wade H. Brown and Louise Pearce of the Rockefeller Institute, who had been inoculating syphilis into rabbits. One of their animals developed a malignant tumour. The histological findings of Brown and Pearce were described in order to illustrate the origin and nature of the growth. Dr. Datnow said that he had found no difficulty in propagating the tumour in English rabbits bought from dealers at random. (The original material was received from Dr. van S. Smith through the courtesy of Professor W. P. Graves of Boston.) He then went on to describe the details of the method of inoculation which he had adopted. The sites of injection were intratesticular, intra-ovarian, intraperitoneal (with a good percentage of "takes"), intramuscular, and subcutaneous (with no "takes" in the small series done). The ovary had not previously been used as a site for grafting, and he found that the tumour remained localized to the ovary for some time before its final and rapid dissemination all over the body. A number of tumour-bearing rabbits had been treated by intravenous injections of lead benzenesulphonylglycinate, in which definite changes ascribable to the lead preparation could be demonstrated. These were illustrated by slides, specimens, and histological preparations. Several rabbits had been completely cured of the tumour, and were quite well. A number of other interesting specimens and lantern slides were discussed.

Reviews

DISEASES OF THE CHEST

Dr. W. J. FENTON and Dr. L. S. T. BURRELL claim that their book on *Diseases of the Chest*,[1] which is written mainly from the clinical standpoint, embodies the personal experience and views of the authors. This claim appears to us to be fully justified. It is a commonplace that the best textbooks are written out of personal experience, and it must be admitted that, from the nature of the case, many cannot fulfil this condition. They often have their genesis in the notes prepared for tutorial classes, when the author's own experience was comparatively small, and, although with increasing first-hand knowledge the personal touch becomes accentuated, still much of the structure is inherited rather than acquired. And so errors are frequently perpetuated by tradition. The fact that this book is so largely a personal record gives it an air of freshness, and makes it agreeable and profitable reading. Even the introductory chapters on the anatomy of the chest and the respiratory mechanism have an individual note, and a critical account of physical signs follows. Next comes an excellent account of pleurisy and its association with tuberculosis. The importance of a broad view of the problems of asthma is emphasized, and the authors state that "in our experience the skin tests have proved of little practical value, and in some cases a severe attack of asthma has even been precipitated by their use." Unfortunately, this must be the conclusion which many have now reached. An interesting account of van Leeuwen's researches on asthma and allergic diseases is given. Further on, the difficult question of allergy in relation to reinfection by the tubercle bacillus is lucidly discussed. In the description of chronic bronchitis the authors express their doubts of the existence of putrid bronchitis apart from bronchiectasis, except as a transient phenomenon. We should entirely agree with this statement; the introduction of more precise methods of diagnosis, particularly the use of lipiodol, has led to the practical disappearance of the diagnosis of putrid or fetid bronchitis in the wards, and its disappearance from the textbooks might very well follow.

The whole treatment of pulmonary disease has assumed a new interest by the invasion of the surgeon into what was for so long regarded as purely medical territory. Until recently most physicians have looked askance at thoracic surgery, except for empyema and occasionally for gangrene of the lung. Even the induction of artificial pneumothorax in the treatment of phthisis encountered much opposition. It seems to us that it was the *x*-ray demonstration of the tuberculous nature of so-called spontaneous pneumothorax which played a decisive part in convincing many of the agnostics on this point. It was realized that this procedure was merely imitating nature's method at a time which could be chosen by the skilled observer, and to-day the advantages of artificial pneumothorax in suitable cases is not contested. But artificial pneumothorax is a "physician's operation." Phrenic evulsion he naturally resigns to a surgeon, but Drs. Fenton and Burrell regard the results of this procedure as disappointing, except as a preliminary to thoracoplasty. We doubt whether this is the general "Brompton" view, however. In the treatment of phthisis the authors consider that it may be of value in testing the state of the other lung. "Should this show signs of activity after phrenic evulsion thoracoplasty should not be proceeded with." But of the more drastic surgical

[1] *Diseases of the Chest*. By W. J. Fenton, M.D., F.R.C.P., and L. S. T. Burrell, M.D., F.R.C.P. London: J. Cape, Ltd. 1930. (Pp. 384; 19 plates. 15s. net.)

methods they regard thoracoplasty as the least dangerous and most hopeful. Pneumolysis, cauterization, and lobectomy are, however, discussed, chiefly in relation to the treatment of bronchiectasis. Indeed, the whole chapter on bronchiectasis is one of the best in the book. Under pneumonoconiosis we do not find any mention of the recent work which tends to show that the inhaled material which is capable of partial solution in body fluids is the most injurious. We conclude that the authors have not confirmed this.

Nearly one-third of the book is devoted to pulmonary tuberculosis, and of this less than one page is given to a discussion of treatment by tuberculin. The authors conclude that, though the dangers of tuberculin have been exaggerated, the chances of improvement by its means are not sufficient to warrant its heroic use. There is one type of case in which it appears to do good without any evidence of harm. It occasionally happens that a patient's temperature will remain between 99° and 100° F. in spite of all efforts to reduce it to normal. Here very small doses of tuberculin given subcutaneously will sometimes be followed by a normal temperature, with no further tendency to rise. There does not appear to be any advantage in large doses should the small dose fail. But this they regard as an example of non-specific shock therapy, which in general can only be used with extreme caution in phthisis. In the discussion of sanatorium treatment we are glad to see the favourable notice accorded to the Papworth Village Settlement, which is especially suitable for those who rapidly respond to sanatorium treatment but cannot maintain their health while under ordinary conditions of employment. Under the protection of sanatorium or colony life such patients are able to live and work, and many bring up a family, whereas they are quite incapable of holding their own and competing in the markets of the outside world. Papworth is a self-contained and growing village. The industries, which are worked entirely by patients, sell the goods in open market, and they are bought on their merits and not out of charity. The sales, which in 1919 were under £4,000, had amounted to £50,000 for the year 1927. After twelve years none of the children brought up in the settlement has developed any form of clinical tuberculosis.

Altogether an admirable book, and produced in the excellent way that one associates with the name of Jonathan Cape.

DERMATOLOGY AND VENEREAL DISEASE

Dr. SCHOLTZ has written a sound textbook of dermatology and venereal disease[2] especially designed to facilitate correct diagnosis for those who will take the trouble to study it. For their sake he provides no fewer than nineteen tables in which the various ills to which the integument is heir are classified from different points of view, so that the practitioner may be aided in the choice of the one which corresponds most exactly with the clinical characteristic exhibited by the patient whose case occupies him at the moment. The first fifteen of these tables deal with the diagnosis of skin diseases according to their primary lesions and their further development; and two other tables illustrate how diagnosis may be aided by the recognition of the most important secondary manifestations. One table is concerned with the differentiation of conditions characterized by excessive irritation, and another shows how the localization of an eruption assists in the diagnosis. Although it is impossible for any tabular scheme to take the place of clinical experience as a means of education in diagnosis there is no doubt that these tables are well and scientifically constructed, and are calculated to be of much use to a practitioner to whom opportunities of learning clinical dermatology by following the practice of a large department are not available.

A very large part of the whole volume is devoted to syphilis, a disease in which the author appears especially to be interested. His views on the treatment in its early stages are a little unusual. He is one of those who still prefer the old and original salvarsan (606) to its later modifications. He is of opinion that it is more effective, and holds that the results he has obtained from its use during the last ten years are ample compensation for the extra trouble which its preparation for use, and the employment of the large volume of solution necessary, involve. He believes in the employment of a comparatively small dose repeated within a short time. He begins his course with three doses of 0.3 gram salvarsan separated only by intervals of a few hours, but he does not give any more until the end of about three weeks and a half, when three further doses, rather smaller, however, than the original three, are administered, and after a similar interval a final series. The administration of three series of salvarsan injections of three doses each does not by any means constitute the whole of the anti-syphilitic treatment. The intervals between the courses are well filled up with bismuth and mercury injections, the administration of Zittmann's decoction, and actinotherapy. For full details the book itself must be consulted, and the arguments brought forward to support this method of using salvarsan will be found worthy of consideration.

In most particulars Dr. Scholtz's volume will be found accurate and up to date, but we are rather surprised that in his account of the treatment of malignant disease of the skin no mention is made of radium. No unprejudiced observer can deny the brilliant results obtained from the use of radium in rodent ulcer, especially in its early stages, and although it has not proved so invariably successful in cases of epithelioma it is without doubt a therapeutic agent of great importance, and deserves full discussion in any work that claims to deal with malignant disease of the skin.

In general, we have no hesitation in saying that Dr. Scholtz's textbook is sound and thorough. It is fortified with a number of prescriptions for the various ailments with which it deals, all collected together as an appendix. Examination of these formulae will provide most readers with useful hints. The illustrations, which form a very important part of any textbook of dermatology, are numerous and clear. The coloured plates for the most part appear to have been taken from wax models, but they are none the worse for that. We have noticed that coloured plates founded on wax models are often more satisfactory than those taken directly from living patients, no doubt because non-essential features are eliminated. Dermatologists and venereologists should add Dr. Scholtz's work to their library, and those general practitioners who live in isolated places will find that the study of its clinical tables will assist them in solving their dermatological problems.

SACRO-COXALGIA

In a recent monograph Dr. PIERRE INGELRANS presents the results of his observations on sacro-coxalgia or tuberculous infection of the sacro-iliac synchondrosis.[3] The tuberculous infection is born by the blood or lymph stream to the centres of ossification in the sacrum or ilium round the joint, very often, if not always, as a consequence of traumatism. It occurs chiefly between the ages of 25 to 35, and is not common below or above these ages. The

[3] *La Sacro-Coxalgie et son Traitement.* Par Pierre Ingelrans. Préface de René Le Fort. Paris: Masson et Cie. 1930. (Pp. x + 140; 6 plates. 30 fr.)

months later, a mass being present in the pelvis. Professor Shaw gave a short account of similar cases which had been recorded.

Mr. N. L. EDWARDS (Derby) demonstrated two specimens. The first was a uterus containing a sarcomatous polypus. A fibroid polypus showing sarcomatous degeneration had been removed a year previously from the same patient, who had at the time refused hysterectomy. The second was a uterus and appendages with a left-sided fimbrial cyst with twisted pedicle and early papilliferous carcinoma of the right ovary.

Professor D. DOUGAL (Manchester) described a case of pseudo-myxoma of the ovaries and peritoneum, referring to two other cases he had previously reported, and giving a brief survey of the literature. In the case at present reported there was no cystic enlargement of the appendix, though a considerable quantity of pseudo-mucin was adherent to it and the caecum. Both ovaries showed large pseudo-mucinous cysts; that on the left side was evidently leaking into the abdomen. The omentum was converted into a cake-like mass, containing many small spaces filled with pseudo-myxomatous material. Both cysts were removed along with the uterus. It was not considered advisable to isolate and remove the appendix. In Professor Dougal's two previous cases the appendix was enlarged and distended with myxomatous material.

Miss RUTH NICHOLSON (Liverpool) described a case of double pyosalpinx in a girl of 16. The patient had been treated for a vaginal discharge at the age of 5. The periods had started at 14, and had been more or less normal. When seen she had a temperature of 103° with a rapid pulse. This continued for fourteen days, when the abdomen was opened and a double pyosalpinx and small uterus were removed. The pyrexia subsided on the third day and the patient made a good recovery. Miss Nicholson was confident in excluding the possibility of a reinfection.

TRANSPLANTABLE TUMOURS

At a meeting of the Liverpool Medical Institution, held on February 12th, with the president, Professor W. BLAIR BELL, in the chair, Dr. M. DATNOW read a paper on a malignant transplantable tumour of the rabbit. The speaker outlined the work of Wade H. Brown and Louise Pearce of the Rockefeller Institute, who had been inoculating syphilis into rabbits. One of their animals developed a malignant tumour. The histological findings of Brown and Pearce were described in order to illustrate the origin and nature of the growth. Dr. Datnow said that he had found no difficulty in propagating the tumour in English rabbits bought from dealers at random. (The original material was received from Dr. van S. Smith through the courtesy of Professor W. P. Graves of Boston.) He then went on to describe the details of the method of inoculation which he had adopted. The sites of injection were intratesticular, intra-ovarian, intraperitoneal (with a good percentage of "takes"), intramuscular, and subcutaneous (with no "takes" in the small series done). The ovary had not previously been used as a site for grafting, and he found that the tumour remained localized to the ovary for some time before its final and rapid dissemination all over the body. A number of tumour-bearing rabbits had been treated by intravenous injections of lead benzenesulphonylglycinate, in which definite changes ascribable to the lead preparation could be demonstrated. These were illustrated by slides, specimens, and histological preparations. Several rabbits had been completely cured of the tumour, and were quite well. A number of other interesting specimens and findings were discussed.

Reviews

DISEASES OF THE CHEST

Dr. W. J. FENTON and Dr. L. S. T. BURRELL claim that their book on *Diseases of the Chest*,[1] which is written mainly from the clinical standpoint, embodies the personal experience and views of the authors. This claim appears to us to be fully justified. It is a commonplace that the best textbooks are written out of personal experience, and it must be admitted that, from the nature of the case, many cannot fulfil this condition. They often have their genesis in the notes prepared for tutorial classes, when the author's own experience was comparatively small, and, although with increasing first-hand knowledge the personal touch becomes accentuated, still much of the structure is inherited rather than acquired. And so errors are frequently perpetuated by tradition. The fact that this book is so largely a personal record gives it an air of freshness, and makes it agreeable and profitable reading. Even the introductory chapters on the anatomy of the chest and the respiratory mechanism have an individual note, and a critical account of physical signs follows. Next comes an excellent account of pleurisy and its association with tuberculosis. The importance of a broad view of the problems of asthma is emphasized, and the authors state that "in our experience the skin tests have proved of little practical value, and in some cases a severe attack of asthma has even been precipitated by their use." Unfortunately, this must be the conclusion which many have now reached. An interesting account of van Leeuwen's researches on asthma and allergic diseases is given. Further on, the difficult question of allergy in relation to reinfection by the tubercle bacillus is lucidly discussed. In the description of chronic bronchitis the authors express their doubts of the existence of putrid bronchitis apart from bronchiectasis, except as a transient phenomenon. We should entirely agree with this statement; the introduction of more precise methods of diagnosis, particularly the use of lipiodol, has led to the practical disappearance of the diagnosis of putrid or fetid bronchitis in the wards, and its disappearance from the textbooks might very well follow.

The whole treatment of pulmonary disease has assumed a new interest by the invasion of the surgeon into what was for so long regarded as purely medical territory. Until recently most physicians have looked askance at thoracic surgery, except for empyema and occasionally for gangrene of the lung. Even the induction of artificial pneumothorax in the treatment of phthisis encountered much opposition. It seems to us that it was the x-ray demonstration of the tuberculous nature of so-called spontaneous pneumothorax which played a decisive part in convincing many of the agnostics on this point. It was realized that this procedure was merely imitating nature's method at a time which could be chosen by the skilled observer, and to-day the advantages of artificial pneumothorax in suitable cases is not contested. But artificial pneumothorax is a "physician's operation." Phrenic evulsion he naturally resigns to a surgeon, but Drs. Fenton and Burrell regard the results of this procedure as disappointing, except as a preliminary to thoracoplasty. We doubt whether this is the general "Brompton" view, however. In the treatment of phthisis the authors consider that it may be of value in testing the state of the other lung. "Should this show signs of activity after phrenic evulsion thoracoplasty should not be proceeded with." But of the more drastic surgical

[1] *Diseases of the Chest*. By W. J. Fenton, M.D., F.R.C.P., and L. S. T. Burrell, M.D., F.R.C.P. London: J. Cape, Ltd. 1930. (Pp. 384; 19 plates. 15s. net.)

condition is discussed systematically, and the chapter on differential diagnosis, which lays stress on the importance of *x*-ray examination, merits special study. The pain is so often referred down the sciatic nerve that a persistent sciatica in young subjects should always suggest the possibility of this lesion. Sacralization of the last lumbar vertebra is a frequent accompaniment.

Treatment is divided into non-operative and operative. The former consists of five possible procedures, none of which find much favour in the eyes of the author: (1) simple immobilization; (2) immobilization combined with horizontal extension; (3) immobilization combined with vertical extension; (4) counter-irritation; (5) punctures for drainage of pus. Operative procedures resolve themselves into arthrodesis, aiming at immobilizing the joint so that the tuberculous process has a chance to heal, and resection of the whole diseased area. Details are given of the technique of both operations. Operative treatment is recommended in young subjects of 14 to 35 years of age in whom the general condition is reasonably good. Arthrodesis is suitable in cases which are still limited and which do not show bone abscesses. Resection operations have always to be adapted to the individual case, since foci of disease may be found in such varying situations round the joint. The author considers that the results of operation are good, but points out that unsuitable cases are sometimes operated upon with disastrous results, but these should not discredit a valuable procedure. Cure always takes about four years, and, serious as the condition is, it is not hopeless. The author has had five deaths in thirty-eight cases.

The monograph is illustrated by a clinical description of the thirty-eight cases, many of these being accompanied by *x*-ray photographs. It is a work to be recommended, not only to orthopaedists (who will naturally be interested in the author's records of his cases of this not very common syndrome), but also to general physicians and surgeons who have to deal with casés of sciatic and sacro-iliac pain. Pain in the back is such a common complaint, and often so intractable, that a clear and succinct description of one of its causes cannot but be valuable.

MEDICAL STATISTICS

The first edition of Professor RAYMOND PEARL'S *Introduction to Medical Biometry and Statistics*,[4] published in 1923, was generally accepted as being an excellent introductory textbook—the type of book that was likely to be of considerable service to students of medical problems who did not wish to lose the advantage that a knowledge of statistical method could give them, but whose knowledge of algebra was limited to memories of their school days. That it is fulfilling this purpose is proved by the issue of a reprint of the first edition in 1927, and by the present need for publication of a second edition. Considerable enlargement and revision of the previous issue have been made. Such sections as those dealing with the international list of causes of death, the movement of the birth rate and the recording of stillbirths, census taking, mechanical tabulation, etc., have been brought up to date. The references for extended reading have been increas[illegible] the more important of the relevant [illegible] with statistics issued during final and [illegible] number of tu[illegible] bearing. [illegible]thod fails because the specific intravenous injections of le[illegible]s required was badly framed, in which definite changes as[illegible]iently collected or recorded. tion could be demonstrated. [illegible]al investigation depends slides, specimens, and histologi[illegible] put in such a way that rabbits had been completely c[illegible] were quite well. A number of [illegible] and findings were discussed.

[4] *Introduction to Medical Biometry and Statistics.* By Raymond Pearl. Revised and enlarged. Philadelphia and London: W. B. Saunders Co. 1930. (Pp. 459; the answer is "correct, precise, clear, and without ambiguity." Statistical analysis—or any form of analysis—is merely waste of time unless this criterion is substantially fulfilled. The author has added an excellent chapter on the essential ideals in the making of scientific records, illustrated by blank forms that he has employed in collecting medical records and in an investigation of longevity, a chapter which should be of considerable help to the potential investigator and enable him to avoid many pitfalls in the collection of material. In the measurement of variation Professor Pearl has developed an interesting graphical method of depicting relative variability for comparative purposes. The coefficient of variation does not, with some workers, readily or instantly call up in the mind an adequate picture of the real degree of scatter of the distribution, so that there seemed to be a sphere of usefulness for a method by which one may *see* the difference or likeness in the variation of a man and a mouse—for example, in respect of body weight. The method adopted is perfectly simple to understand, and, judging by the examples given, effective in practice.

The author and his co-workers have done in recent years a great deal of valuable work on the problems of the growth of populations, and it is fitting that a chapter should have been added on the logistic curve. The book remains practically devoid of algebra, and should continue admirably to fulfil the wants of those who visibly wilt at the introduction of *x* and *y*.

HYPERTENSION AND HYPOTENSION

The work on *Hypertension*,[5] by Dr. LESLIE T. GAGER, professor of clinical medicine in the George Washington University, may conveniently be noticed with that on Acute and Subacute Hypotension[6] by Dr. M. A. DUMAS of Lyons, which reproduces a communication made to the twentieth French Congress of Medicine held at Montpellier in 1929. Dr. Gager's monograph, which is based on personal observations and a study of the literature as evidenced by his carefully chosen bibliography of 505 references, gives a full account of hypertension, including the historical aspects, etiology, clinical phenomena, prognosis, and treatment. It forms a good up-to-date presentation of the subject, and should prove very valuable as a work of reference. Dr. Dumas's book on hypotension is divided into four parts, devoted respectively to a general consideration of the subject, symptomatology, conditions under which hypotension may occur, and diagnosis and treatment. A classified bibliography, consisting almost exclusively of references to French literature, is appended.

NOTES ON BOOKS

The call for a second edition of *The Treatment of Chronic Deafness by the Electrophonoïde Method of Zünd-Burguet*,[7] by Dr. GEORGE CATHCART, shows that although the method which he advocates has been met by much opposition and some criticism, he has nevertheless secured an appreciable following. Little change has been made in the new edition, but a larger number of results are now available. The original details of 100 cases with 68 per cent. improvement are given, but the total is now 665 cases, with 64.5 per cent. improvement, showing a remarkable continuation of uniform results. Dr. Cathcart still maintains that there is an unknown factor in deafness, apart from the known anatomical abnormality, and that this factor accounts for the success

[7] *The Treatment of Chronic Deafness by the Electrophonoïde Method of Zünd-Burguet.* By George C. Cathcart, M.D. Second edition. Oxford Medical Publications. London: Milford, Oxford University Press. 1931. (Pp. xiii + 111; 7 figures. 5s. net.)

of the Zünd-Burguet treatment. We have previously suggested that this factor may be functional, but the fact remains that the method is capable of relieving a certain number of deaf people, and of alleviating their tinnitus. Dr. Cathcart takes the opportunity in a long preface to reply to some of the critics of the first edition. He need not have done this, because the method will eventually survive on its merits or perish by its failures; but he himself has full confidence in its worth, and his method of dealing with critics has some educational value.

Messrs. Jonathan Cape have now published an English translation, by Dr. Helen C. Scott, of the well-known book on *Clinical Examination and Surgical Diagnosis*,[8] by Professor FÉLIX LEJARS. A review of the second French edition appeared in the *Journal* of November 12th, 1927 (p. 883). The English edition is particularly well illustrated, and the practical way in which the various descriptions are set out will cause the book to be very welcome to readers in this country.

Several important French books on different aspects of renal disease have recently been noticed in these columns, and we now have for review a large monograph by CHABANIER and LOBO-ONELL on the investigation of renal function.[9] This book emanates from the Hôpital Necker, Paris, and is dedicated to Legren and Ambard, distinguished teachers of this hospital. As would be expected, therefore, many pages are devoted to the "Ambard constant," and this book gives us an excellent opportunity of reading in summarized form all the views and methods of Ambard and his associates. There is an admirable bibliography placed at the bottom of each page. The book is interesting to specialists, but is scarcely suitable for reading by the general physician.

The title of the book Rejuvenation through Stimulation of Blood Production,[10] by Dr. ARNOLD LORAND, is misleading; neither rejuvenescence nor blood production, as is generally understood by these expressions, is considered. This is not a scientific treatise. It is a collection of general vague statements and opinions of the author on diet and various therapeutic measures which would probably confuse rather than help the medical practitioner in the treatment of his patients. The book is perhaps only intended for the lay reader.

Almost from time immemorial arsenic has been instrumental in providing the world with those impassioned dramas of real life which grip the imagination more than anything else—the trial of one human being for the murder of another. The struggle of the accused, often with inadequate forces at his disposal, against the might of the Crown, never fails to thrill the imagination of the public. The *Trial of Harold Greenwood*[11] for the murder of his wife in 1920 supplies all the ingredients for a sensational drama, together with a mystery which remains unsolved. Did Mrs. Greenwood die from arsenical poisoning, from opium poisoning, or from natural causes; and if from poison, whose was the hand which administered it? In the series of "Notable British Trials" an endeavour is always made to present as nearly as may be a verbatim report of the judicial proceedings, and it is only in the introduction that the author has any opportunity of displaying his individuality. WINIFRED DUKE, in her introduction to the Greenwood case, epitomizes the whole subject in a very readable manner, and has given a careful verbatim report of the trial, together with the proceedings at the coroner's inquest and the police court. The book will no doubt appeal to the general reader as much as to the student of crime.

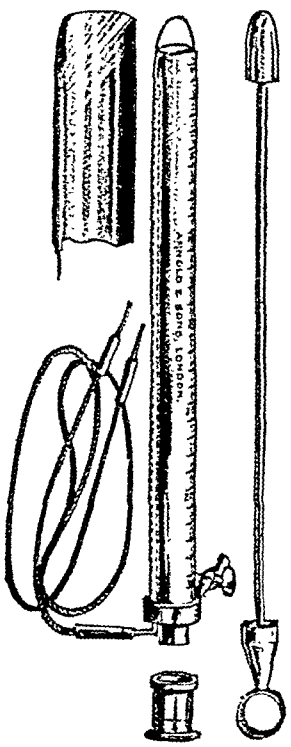
The eleventh edition of MARSHALL'S *Junior Course of Practical Zoology*[12] has been revised by H. G. NEWTH of Birmingham University. We have already commented in these columns on the excellence of this compact volume as a laboratory guide to elementary zoological studies. In the new edition, except for a brief note on nyctotherus and balantidium in the chapter on protozoa, no new types of animals have been introduced, but all the operations described in the textbook have been performed again to ensure the accuracy of the technical instructions.

[12] *A Junior Course of Practical Zoology*. By the late A. Milnes Marshall, M.D., D.Sc., F.R.S., and the late C. Herbert Hurst, Ph.D. Revised by H. G. Newth, M.Sc. Eleventh edition. London: J. Murray. 1930. (Pp. xvii + 519; 94 figures. 12s. net.)

PREPARATIONS AND APPLIANCES

A SIGMOIDOSCOPE

Mr. FRANK HARVEY, F.R.C.S. (London, W.) writes: I have devised, with the technical assistance of Mr. Olliver of Messrs. John Bell and Croyden (Arnold and Sons), 50-52, Wigmore Street, a modification of the Lockhart-Mummery sigmoido-



scope. The lamp, instead of being on a long stem, inside the lumen of the instrument, is recessed in its walls, and protected by a window, which is situated a short distance from the distal end. The advantages of this arrangement are that the lamp and holder cannot be fouled by faeces, nor can the swabs be caught in the lamp. When the lumen of the sigmoidoscope does become soiled the one action of cleaning the instrument also cleans the window behind which the lamp is recessed and protected.

I have also had a rectal speculum made on the same principle.

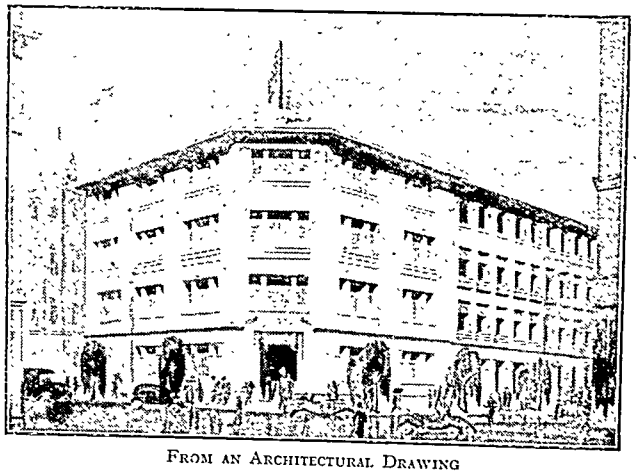
THERAPEUTIC BACTERIOPHAGES

The products of Le Laboratoire du Bacteriophage, which is under the control of Professor d'Herelle, are being marketed in this country by the Anglo-French Drug Co., Ltd. The discovery of the bacteriophages is one of the most interesting advances that have been made this century in immunology. If the claims of Professor d'Herelle are justified the discovery is a therapeutic advance similar in importance to the discovery of antiserums. The therapeutic value of these preparations is, however, still obscured by controversy. The subject is far too difficult, and also too important, to attempt to adjudicate upon in a short note. Some of the bacteriophages which are now being introduced for general use in this country are: bacte-coli-phage, bacte-pyo-phage, and bacte-intesti-phage.

ALL-INDIA INSTITUTE OF HYGIENE AND PUBLIC HEALTH

GIFT OF THE ROCKEFELLER FOUNDATION

Prior to 1920 medical graduates in India had to go abroad for systematic study of tropical medicine and hygiene. The idea of establishing institutes in India for this purpose, however, had been conceived in 1914 by Sir Leonard Rogers, who proposed that there should be a School of Tropical Medicine in Calcutta and an Institute of Hygiene in Bombay. Although circumstances prevented the realization of these projects, Rogers's perseverence and enthusiasm, aided by the generosity of the Governments of India and Bengal, and various private benefactions, led to the opening in 1920 of the Calcutta School of Tropical Medicine and Hygiene, in which teaching and research were combined. A chair of hygiene was established, and a course of instruction arranged for the university diploma of public health, but this provision was soon seen to be inadequate. It was recognized that as time went on, and public health policy expanded in all the Indian provinces, there would be an increasing need for specialists and workers highly trained in general hygiene, with knowledge and experience of Indian requirements. This matter was referred to by Major-General J. D. Graham in his annual report as public health commissioner in 1925:



FROM AN ARCHITECTURAL DRAWING

"This is a work which has to be done for the benefit of Indians. To be effective it must carry conviction and establish its position against immemorial conservatism and tradition; it must therefore be done by Indians. It presents a grand and unlimited field for public health workers, but it is well to recognize that the improvement cannot be achieved when the expert labourers are too few in number, that these cannot be increased to the requisite number without a careful system of specialized training in institutes or schools devoted to public health teaching and research. . . . It has often been represented, and not without justice, that scientific knowledge in regard to the prevention of certain communicable diseases has far outstripped its application in the field. It is with such a personnel that the practical application must finally rest."

These conclusions, repeatedly endorsed by Major-General Megaw, head of the school, were discussed with Dr. W. S. Carter, associate director of the Rockefeller Foundation, during his periodic tours of India and the Far East, with the result that he became deeply impressed with the necessity of establishing an All-India Institute. Much of the teaching in basic subjects, such as bacteriology and protozoology, being common to the diplomas of public health and of tropical medicine, the advantages were obvious of establishing the institute in Calcutta on a site close to the school, where the basic subjects would continue to be taught, the institute being concerned with subjects especially related to Indian requirements. The Rockefeller Foundation offered to meet the cost of acquiring the site, and to build and equip an institute on an assurance from the Government that it would defray the cost of staff and maintenance after the building was handed over.

In July, 1930, a site was acquired, and building was begun in September. A constructional committee was appointed, consisting of the public health commissioner with the Government of India, the surgeon-general with the Government of Bengal, the chief engineer with the same Government, the chairman of the Calcutta Improvement Trust, and the Accountant-General, Bengal. Lieut.-Colonel A. D. Stewart, professor of hygiene in the Calcutta School of Tropical Medicine, was appointed director-designate of the new institute, and Lieut.-Colonel A. A. E. Baptist assistant director, to superintend the construction and equipment. It is expected that the building will be completed by the end of this year, and that the institute will be opened for work early in 1932.

The site of the institute practically adjoins the school, with which the building will harmonize in design and appearance. The plan is based on a unit room of 25 ft. by 21 ft. The building, which will be E-shaped and four-storied, the long limb being in the centre, will accommodate six sections: (1) public health administration; (2) sanitary engineering; (3) vital statistics and epidemiology; (4) biochemistry and nutrition; (5) malariology and rural hygiene; and (6) maternity and child welfare and school hygiene. Each section will be allotted one unit room for the head of the section and two unit rooms for the workers. The working sections will be placed in the central limb of the building facing north, with unimpeded north light. The west block will comprise the administrative rooms, lecture theatre, practical class rooms, museum, and a large auditorium to seat 200. In the east limb there will be store rooms, a common room, and a lunch room for students, spare working rooms, and lavatories; a separate annexe will provide for an animal room on each floor. The library will be in the centre block on the top floor. Three unit rooms on each floor, and the library and reading room, will be supplied with conditioned air during the hot months of the year.

Each section will be staffed by a professor, an assistant professor, and laboratory or other assistants. As the chief object of the institute is to bridge over the gulf between the results achieved by pure research and their practical application to the community, its function will be primarily instruction. The subjects for the D.P.H., Part I, will continue to be taught at the Tropical School, but the specialized subjects in public health will be taken by the staff of the institute. The examination for the D.P.H. is conducted by the University of Calcutta, with which the new institute will in due course be affiliated. It is also intended to provide short post-graduate instruction in special subjects for public health workers desiring to pursue advanced study, and it is probable that the University will institute a higher degree or doctorate in public health science, which will require a year's training at the institute in some specialized branch. Special courses in child welfare and public health nursing may be arranged for women graduates and nurses respectively. The institute will be co-ordinated with the various aspects of practical hygiene and public health all over India, and will, it is hoped, render assistance to public health administrators and workers, and organize and carry out investigations in the application of medical research and knowledge for the betterment of the Indian people.

THE THYMUS PUZZLE

The thymus gland still remains one of the puzzles of medical science, and authorities differ widely both about its exact importance in the physiology of the human organism and about its significance in disease. In opening a discussion on this subject at the International Paediatric Congress in Stockholm last summer, Professor E. Moro of Heidelberg sketched an imaginary conversation between an average doctor and a research worker studying the thymus, out of which emerged the conclusion that concerning the functions of this gland and their importance for the organism nothing is known for certain to-day! Professor Moro hastened to add, however, that a great deal of knowledge about the thymus had been patiently accumulated, and in many ways the ground had been cleared, although the results of many animal experiments were contradictory.

In his paper, which has now been published,[1] Moro deals particularly with the thymo-lymphatic system from the clinical standpoint. He describes three clinical divisions: congenital hyperplasia of the thymus, status thymico-lymphaticus, and status lymphaticus. He does not deal with the first because, in his opinion, it has nothing to do with status thymico-lymphaticus, which was the particular subject under discussion. The second and third clinical conditions he would keep strictly separate. In other words, the term "status lymphaticus" stands for the lymphatic type of child, of the "exudative diathesis," with hyperplasia of the whole lymphatic apparatus of the body, including a lymphocytosis in the blood. In this "fat and flabby" type of child the enlarged thymus is a part of the clinical picture, but the liability to sudden death is not a feature of this condition. On the other hand, in status thymico-lymphaticus the sudden failure of the action of the heart is, in Moro's view, the central point of the whole thymus problem, and he considers a better term for the condition would be "status cardio-thymicus." He discusses the possible connexion between the thymic enlargement and the cardiac failure, mentioning hyperthymization, dysthymization, hormonal dysharmony, and an anatomical, nervous theory as possibilities to be considered. Whatever the true explanation, he is convinced that status thymico-lymphaticus is a definite pathological condition—a conclusion first suggested some thirty years ago by his teacher Escherich, and very much out of fashion to-day. Indeed, as was recently reported in these columns (March 14th, 1931, p. 468), the opinion of the committee set up jointly by the Medical Research Council and the Pathological Society of Great Britain and Ireland is emphatically against such a conclusion. Incidentally, Professor Moro observes that the condition is much less often seen nowadays in Germany than it used to be. In contrast with this, congenital hyperplasia of the thymus seems to be very much on the increase, especially in the North American continent, and some authorities have reported that over 40 per cent. of infants show an enlarged thymic shadow when examined with *x* rays.

Dr. A. Stanley Kirkland, in a recent paper from Canada,[2] discusses particularly this congenital condition, dividing all children with thymic symptoms into three age groups: those who have difficulty in the first few hours of life; those whose difficulty appears in the early weeks of life; and those whose persistently enlarged or hyperfunctioning thymus endangers their lives during the years up to puberty or even later. He especially discusses the second group, and the clinical picture he describes is that of a child in the first months of life who has difficulty in feeding, associated with some cyanosis and dyspnoea, who chokes when crying, and may have a crow or inspiratory stridor. *X*-ray examination of such a child will, in the majority of cases, show an enlarged upper mediastinal shadow, and treatment by means of *x*-ray therapy rapidly restores the child to normal. This picture of what has been called "thymic asthma" is certainly not seen at all frequently in this country, and it is difficult to believe that it is not being recognized. Indeed, some children's physicians, on clinical as opposed to radiological grounds, deny the existence of the condition except as an extreme rarity, and it is interesting to observe Kirkland's remark that "the *x*-ray demonstration of a large thymus shadow is only part of the picture," and such demonstrable enlargement is not essential for diagnosis. In cases where a shadow is present it may remain exactly the same size after *x*-ray treatment, although the symptoms have been relieved by irradiation of the gland. These alarming symptoms ascribed to "thymic dysfunction" may therefore have nothing definitely to do with the thymus gland, notwithstanding that empirical treatment of them by irradiation of the thymus seems effective.

These results are well in accord with Moro's view that present-day knowledge of the thymus is anything but certain. It seems to be impossible to obtain precise figures for the normal size, shape, or weight of the gland at different ages, which can be agreed upon by anatomists, paediatricians, and radiologists. The latest investigation in this country, referred to above, had as one of its objects the establishment of standards of weight for age and proportion to body weight of the normal thymus at all ages; but, even granted that the results are universally accepted, the difficult question of the radiological shape and size of the normal gland is still unsettled. While these elementary points remain obscure it is not surprising that wide disagreement exists over such conditions as congenital hyperplasia of the thymus and status thymico-lymphaticus.

THE CAMPAIGN AGAINST SILICOSIS

Dr. E. L. Middleton, in a report lately issued by the Home Office,[1] gives an interesting summary of the findings of the International Conference on Silicosis, held at Johannesburg last August, of which some account appeared in our issue of October 4th, 1930 (p. 567). Dr. Middleton was the official representative of Great Britain at that conference. He describes the long campaign conducted since 1902 in South Africa against the disease, and the remarkable success which has attended those efforts. The last figure (that for 1928–29) of the number of white miners affected with silicosis is 1.76 per cent. This represents a genuine improvement, because it has been brought about in the face of continued increase in the number of miners at work.

During the twelve years' period of activity of the Miners' Phthisis Medical Bureau, 4,362 cases of silicosis, and 382 cases of tuberculosis with silicosis, have been detected in the Union of South Africa. As we remarked a few weeks ago, when reviewing the last annual report by its chairman, Dr. Louis G. Irvine, the Bureau deals with conditions which exist in no other country, and no student of tuberculosis or industrial medicine can afford to neglect its reports. These documents are particularly important because they record, year by year, the progress of the fight against silicosis, and indicate how far the preventive measures against dust in the mines are successful. The conclusion arrived at by the conference as to causation was that "silica must reach the lungs: (*a*) in a chemically uncombined condition, although the dust inhaled may be mixed with other dusts either as a natural mixture, such as occurs in granite, or as an artificial mixture; (*b*) in fine particles, though there is no evidence as to the lowest limit of size of particles capable of producing the disease; (*c*) in sufficient amount and over a certain period of time." Contradictory views, however, were held as to prognosis. In South Africa the general opinion is that the disease is not arrested on ceasing employment, while in Great Britain there is evidence that if a person were removed from exposure at the earliest detectable signs, the disease would not generally progress, at least, over a considerable number of years. In regard to compensation, the important practical conclusion was reached that "where legislation provides for the compulsory removal from occupations involving exposure to silica dust of workers affected by silicosis, such compulsory removal should not necessarily be applied to workers who have been in the same industry for a period of not less than fifteen years and have reached the age of forty-five years." This recommendation was obviously prompted by the intolerable hardship inflicted on the skilled worker, who, at a comparatively advanced age, would find great difficulty in obtaining alternative employment. Water sprays were considered to be of little value for removing fine dust from the air, and their employment has other objections, but the use of localized exhaust draught was of great value. Indeed, as Dr. Irvine has said in one of his reports, the fine dust requires to be treated as a gas. One of the great aims of the Conference on Silicosis was to promote international co-ordination in the outlook on this disease, in the description of it, and in the means for its prevention; and, as Dr. Middleton says, the discussions by experts at Johannesburg last summer went far to bring this about.

Publication of Dr. Middleton's report coincided with the delivery in London of a Chadwick Public Lecture by Mr. E. A. Elsby, on preventive methods against silicosis.[2] Mr. Elsby is the happy possessor of one of the newly instituted Chadwick Travelling Scholarships, and has made good use of his time in the United States. He looks at silicosis and its prevention from the point of view of the engineer, and is quite right in saying that the weakness of all legislation on this subject lies in the fact that no limiting concentration of silica dust in the atmosphere has been laid down. This omission is a serious handicap to factory inspector and manufacturer alike in their efforts to determine what are satisfactory conditions. He would like to see adopted, as has been suggested by A. E. Russell[3] for granite, a permissible dust standard of 10 million particles per cubic foot of air. Seeing that granite contains only 30 to 40 per cent. of free silica, the limiting concentration, calculated in terms of 100 per cent. free silica and of particles less than 10 microns in size, would be 3 million per cubic foot of air, a figure which can be obtained in industry with correctly designed plant. In his lecture Mr. Elsby showed how important in this connexion is the correct design of hoods and ducts for the removal of silica dust.

"A DEVELOPING SYSTEM"

The object of the Bill for the Registration and Regulation of Osteopathy[1] is stated in its Memorandum to be "to place the practice of osteopathy, as a developing system of treatment of disease by manipulative methods, under the control of a statutory board with power to enforce a prescribed standard of education and professional competence upon all osteopathic practitioners." This private members' Bill is framed on the model of the Dentists Act, the Midwives Acts, and the Venereal Diseases Act, as opposed to that of the Medical Acts—that is to say, it not only seeks to regulate the assumption of titles, the holding out of practitioners as duly qualified, and the recovery of fees, but to prohibit the actual practice of the specialty by persons not on the proposed register. But the Bill goes far beyond the Acts mentioned. Section 2 (2) defines the term "practice of osteopathy" for the

[1] A Bill to Regulate the Practice of Osteopathy and to Prescribe the Qualifications of Osteopathic Practitioners. (Bill 93.) London: H.M. Stationery Office. 1931. (4d. net.)

FIG. 1.—Showing the homogeneous filling of the diverticula.

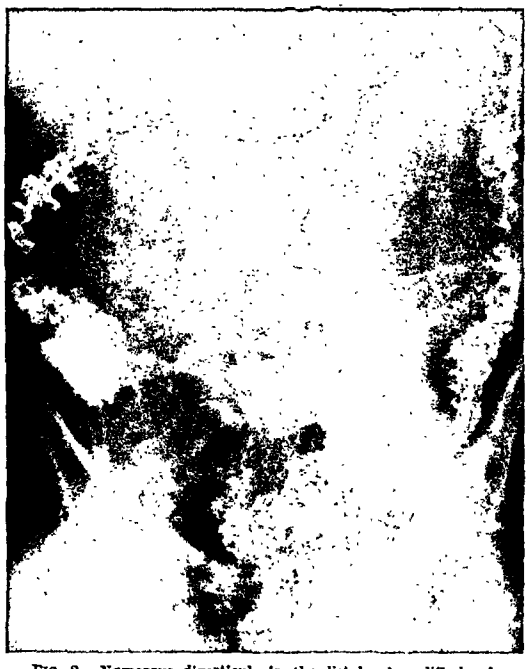

FIG. 2.—Numerous diverticula in the distal colon, differing from those seen in Fig. 1, in that they do not fill homogeneously, but show a central translucency and a peripheral opacity.

FIG. 3.—Postero-anterior view. Note the seemingly normal ascending colon and the apparent "kink" in the descending colon.

FIG. 4.—Same case as in Fig. 3. Radiogram taken in the right oblique position. Note redundancy of ascending colon. A filling defect, if present in such a loop, might be overlooked in the postero-anterior view.

FIG. 5.—Left oblique view. Same case as in Figs. 3 and 4. Apparent kink in Fig. 3 is here shown to be a smooth curve. The diverticula are indicated by arrows. The whole extent of the sigmoid colon is seen only in this figure and in Fig. 4.

FIG. 6.—Postero-anterior view, showing an apparently normal colon.

FIG. 7.—The same case as in FIG. 6, but shown in the left oblique position. Note the numerous diverticula, completely concealed in Fig. 6.

FIG. 8.—Showing the cessation of the double outline in the constricted area.

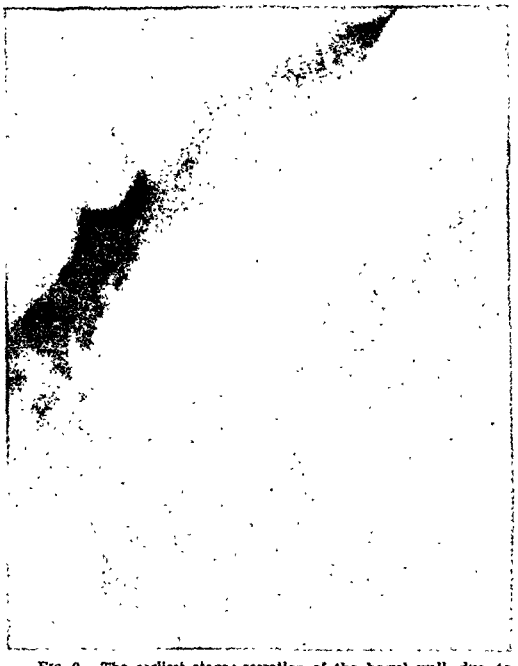

FIG. 9.—The earliest stage: serration of the bowel wall, due to "diverticular buds."

FIG. 10.—A later stage: "diverticular buds," together with some fully formed small diverticula.

FIG. 11.—Large diverticula, small diverticula, and "buds."

FIG. 12.—Showing numerous diverticula throughout the colon, a few being present even in the appendix.

FIG. 1.

FIG. 2.

purposes of the Act. This is to "include the performance of any such operation, and the giving of any such treatment or attendance, as is commonly given by osteopaths, and any other necessary measures required for the efficient performance of osteopathy." Section 7 provides that (with certain limitations in the case of persons registered on a three years' bona-fide practice of osteopathy prior to the passing of the Act) a person on the Register of Osteopaths shall be entitled to practise and hold himself out as practising osteopathy, to recover fees for his services, to sign birth and death certificates, and, subject to special authorization, to administer anaesthetics and perform minor operations. Since the osteopath is essentially a manipulative practitioner, undertaking manipulations of all kinds, it would seem that this special authorization to perform minor operations must extend beyond manipulation to cutting operations, otherwise it is difficult to understand the distinction between the registered osteopath entitled to the practice of osteopathy and the registered and specially licensed osteopath who may *also* administer anaesthetics and perform minor operations. These short definitions must be read in conjunction with the second schedule, which lays down the "subjects in which osteopaths are to be qualified" and the minimum hours of study in each of them. Here alone do we find mention of the principles of osteopathy, as opposed to the practice with which the Bill deals on a severely practical basis. As regards practice, we find a long definition which includes "diseases of nervous system, psychiatry, alimentary tract, heart and vascular system, genito-urinary diseases, ductless glands and metabolism, respiratory tract, bone and joint diseases, corrective gymnastics, acute and infectious diseases, pediatrics, dermatology, syphilis, diagnosis (physical, laboratory, and differential), and clinical practice case recording." Minor surgery—for which it is true special licence is needed—is to include "fractures and dislocations, principles of surgery, and surgical diagnosis, orthopaedic, orificial, clinical, with anaesthetics." The osteopath is also to be qualified in "eye, ear, nose and throat, gynecology, obstetrics, professional ethics and efficiency, and jurisprudence," as well as in "hydrotherapy, *x*-radiance and electrical diagnosis," and in such minor branches of medicine as pathology, bacteriology, and hygiene. Unlike the Midwives and Dentists Acts there is *no* saving clause in favour of persons included in the *Medical Register*. It is difficult, therefore, to escape the conclusion that, whether by accident or design, the terms of the Bill would in fact deprive duly qualified medical practitioners of the right to undertake practice in any of the subjects included in the "practice of osteopathy" as defined in Section 2 (2) and Schedule 2, and possibly also in the list of special diseases quoted above, for it is not easy to see why the osteopath should be qualified in these special subjects if practice of them is not to be included in the practice for which he is to be considered legally competent. This attractive if unusual disregard for vested interests (outside the ranks of osteopaths) is crowned by a special provision to ensure that osteopathy "as a developing system of treatment of disease" shall be untrammelled by any possible influence from the obscurantist medical schools. It is expressly laid down that the two representatives of science to be appointed to the osteopathic "Board," by the Minister of Health and the Scottish Department of Health respectively, *shall* not be registered medical practitioners. Truly a remarkable Bill.

THE TRAFFIC IN DANGEROUS DRUGS

Next May yet another international conference on the traffic in dangerous drugs is to be held in Geneva. Meanwhile, the League of Nations Advisory Committee on Opium, as requested by the Assembly, has, at a recent meeting, been preparing plans for the new conference, including a draft convention intended to effect a limitation of the manufacture of narcotic drugs to medical and scientific requirements. It will be remembered that a conference composed of representatives of the manufacturing countries, which met in London last October, failed to arrive at an agreement as to the apportionment of "quotas" to each producing country of the total required for world consumption. While the "quota plan" is favoured by the Advisory Committee, and this is to form the basis of discussion at the May conference, it is understood that the consideration of an alternative plan of "stipulated supplies" will not be precluded from consideration. The latter plan provides for the consuming countries to declare in advance their legitimate requirements and to name the producing countries from which they will obtain them, and claims to preserve an "open market." The draft convention appears to be an elaboration of the international obligation prescribed in Article IX of the Hague Convention, which reappeared as Article V of the Geneva Convention. It bound the contracting Powers to enact pharmacy laws to limit exclusively to medical and scientific purposes the manufacture, sale, and use of morphine, heroin, cocaine, etc., and to co-operate with one another to prevent their use for any other purpose. Further machinery is suggested in the shape of a central narcotic bureau to supervise the international traffic; the composition of the bureau is to be left to the May conference, but the two bodies already in operation—namely, the Advisory Committee and the Central Opium Board—are to be represented on the bureau. Although most of the manufacturing countries in the world (with a few important exceptions) are bound by the articles of the Hague and Geneva Conventions, the illicit drug traffic is still of "alarming dimensions," and the Central Board, at its recent meeting, was led to question whether drugs ostensibly designated for medical use were not being diverted to illegitimate purposes. The Council of the League has advised the Board to endeavour to secure fuller and more up-to-date statistical returns, and to ascertain from Governments how confiscated narcotics are disposed of. A report of the Commission dispatched to the Far East to report on the "suppression" of opium smoking, as contemplated by the Hague Convention of 1912, was considered by the Council of the League at their January meeting. The report, which consists of four volumes, three of which are still in the press, appears to recognize "the inevitability of gradualness" in the "suppression" of opium smoking. Attention was again directed to the excessive cultivation of the opium poppy and to the extent of smuggling that goes on, and this is put forward as an excuse for delay in the suppression policy. The Persian representative reiterated

the need for financial aid to his Government if opium is to be replaced by less harmful and less remunerative crops. The Portuguese representative was concerned lest the Budget of the Government of Macao would not balance if deprived of the revenue from opium, while the Chinese representative demurred to comments on poppy cultivation in China, seeing that the Commission had refrained from visiting his country. It would seem, therefore, that " the gradual and effective suppression " of opium smoking, adumbrated in 1912 by the Hague Convention, is not yet within sight.

REGISTRATION OF BLOOD DONORS

For many years in New York and other cities in the United States of America a class of " professional blood donors " has been growing up in an unregulated manner. In the past a considerable proportion of these donors must have subsisted on a demand for the frequent, but relatively small, transfusions given to patients with pernicious anaemia. This demand has been to a large extent eliminated by the introduction of other forms of treatment for this disease, but it seems that professional donors have nevertheless multiplied, and agencies have arisen for their exploitation. The Department of Health of New York City has now taken cognizance of certain unspecified evils that have crept into the practice of commercial blood donor agencies, and of the necessity for controlling them. Regulations have accordingly been drawn up, which were adopted by the Board of Health in November, 1930. The matter is of interest, as there was no precedent for the official recognition of blood donors. According to these regulations, a blood donor agency must apply for a permit to practise, and must keep full records of every donor employed and every transfusion performed. Each donor must have a certificate issued to him by the Department of Health, and it is laid down that no donor shall be used for transfusion whose blood has a haemoglobin content of less than 85 per cent. The prospective donor has first to make an application for registration, in which he has to state that he has never been affected with syphilis, chancre or chancroid, malaria, asthma, tuberculosis, or heart disease, and is not addicted to the use of drugs. He is then fully examined by a physician, who has to record a series of personal characters and the condition of all the important organs. The blood group is tested by a laboratory director and recorded under all the current systems of notation. Lastly, a " luetic test " is made by the Department of Health and recorded. These formalities having been satisfactorily concluded, the donor is given a registration book, in which the necessary details of the test are entered. The book further contains forms for entering a record of his physical condition before every transfusion, and of details of each transfusion performed. Given the fact that abuses have grown up, these regulations seem well designed to deal with them. It is necessary to safeguard the interests of both patients and donors, and it is probable that other countries and cities will, before long, follow the lead given by New York City. The provision of blood has not hitherto been commercialized in Great Britain, but even with voluntary donors, such as those of the London Blood Transfusion Service, the same care has to be observed.

OPERATIVE TREATMENT OF SCOLIOSIS

The complex of deformities usually included under the term scoliosis is, when of advanced degree, so disturbing and unsightly that it has always been a supreme desideration of the orthopaedic surgeon to remedy, or, if remedy is out of reach, to prevent it. In the Eastern States of North America great epidemics of anterior poliomyelitis have left behind them a number of cripples altogether beyond comparison with that caused by the disease in this country. Among the resultant deformities, a proportion have been caused by paralysis of muscles of the trunk, the outcome of which has been scoliosis with bone deformity. Further, the populations of mixed races in the United States appear to give origin to a large number of cases of scoliosis due, not to a discoverable palsy, but to developmental defects of the skeleton. In short, in one way or another a large field for experiment and cure has been provided for American surgery. Since June, 1914, Dr. Russell A. Hibbs[1] of New York has been treating scoliosis by the method of fusion of spinous processes, which he originally introduced for the treatment of tuberculous disease of the vertebrae. In 1924 he published a report of 59 cases so treated, and has now given us the results in 360 cases dealt with between the years 1914 and 1927. In 44 of the cases there was definite evidence of paralysis, and 4 were examples of congenital anomaly, but in the remainder the causation was obscure, although Dr. Hibbs has grounds for thinking that the deformity may have been due to unbalanced muscular action. Rickets could not be assigned as a cause in any case. In 427 operations there were 7 deaths, a mortality of 1.6 per cent. This is not an appalling figure, yet it must be remembered that scoliosis is not in itself immediately dangerous to life, and that it is not justifiable to run grave risks in such cases. The rationale of the procedure is the maintenance, by factitious ankylosis, of such correction of deformity as can be made, and the prevention of its increase during growth or by faulty posture. As 113 of the cases reviewed had been operated upon ten to fifteen years previously, we should expect that the investigation would yield information of results which might be considered permanent. Dr. Hibbs and his coadjutors conclude from this review that spine fusion maintains correction of a progressive lateral curvature and prevents its increase. For from six to twelve months after operation constant support is necessary. In order not to undo previous good work of correction, the operation is performed through a posterior fenestration of the supportive cast. In the authors' hands the best form of correction of lateral curvature has been a combination of head and pelvic traction with complete lateral bend, accomplished by means of an anteroposterior turn-buckle hinged plaster jacket. Such operations do not profess to remedy all the complicated deformities which characterize a severe case of scoliosis, but by attacking successfully the lateral curve and to some extent the rotation of the bodies of the vertebrae they mitigate or even abolish the worst and most objectionable features of the distortion.

[1] Scoliosis treated by fusion operation, etc., by Russell A. Hibbs, M.D., New York, N.Y.; Joseph C. Risser, M.D., New York, N.Y., Fellow of New York Orthopaedic Dispensary and Hospital; and Albert B. Ferguson, M.D., New York, N.Y., Director, Department of Roentgenology, New York Orthopaedic Dispensary and Hospital. *The Journal of Bone and Joint Surgery*, January, 1931, p. 91.

PEKING MAN

Since his return "from a mission of ancestor worship in China," Professor Elliot Smith has spared no pains to place the results of his mission before the English-speaking public. These results, bearing on the nature of that primitive fossil type of humanity now known as Peking Man (*Sinanthropus pekinensis*), are fully set out in the reprint of a lecture[1] delivered in the University of Edinburgh, and given under the aegis of the Henderson Trust. A full account of the events which led up to the discovery of this ancient type of man is most welcome. Professor Elliot Smith, in common with most anatomists, is of opinion that "the brain-case found by Mr. W. C. Pei at Chou Kou Tien on December 2nd, 1929, is the most significant and illuminating relic of primitive man ever discovered." In importance Peking Man takes rank with Java Man and Piltdown Man; it is Professor Elliot Smith's view that the ancient Chinese type serves to bridge the structural differences between the ancient types of England and of Java. The discovery in China has also given "a particularly welcome corroboration of the general accuracy of the argument" which Professor Elliot Smith put forward at the Dundee meeting of the British Association in 1912—namely, "that in the evolution of man the growth of the brain preceded the transformation of the face and body. The cerebral cortex acquired functions distinctive of the human status at a time when the organism as a whole still retained many simian characters. The earliest men were essentially big-brained apes." The lecture is well illustrated by excellent figures drawn from official sources, and full acknowledgement is made by the author of his indebtedness to Professor Davidson Black, who is making a detailed study of the various cranial fragments so far discovered at Chou Kou Tien, and who, in due course, will issue a comprehensive report on Peking Man.

RADIOGRAPHY OF THE ACCESSORY NASAL SINUSES

By means of a cinematograph film, Dr. H. K. Graham Hodgson described to the British Institute of Radiology on March 19th a new standardized technique which he has evolved for the complete examination by *x* rays of the accessory nasal sinuses. These sinuses, said Dr. Hodgson, had been called the radiologist's "no man's land," but, before dismissing radiology as of little value, it was well to consider the alternative aids to diagnosis, such as transillumination and proof puncture. The former could not be as accurate as radiology, because one had to deal with light reflected through the antrum or sinus, while as to proof puncture, if the antrum should be filled with polypi, no pus would be obtained, and the method would be valueless. He had devoted himself, therefore, to an improvement of the radiological method with a view to making it more useful to the laryngologist. A standard technique was the first necessity. In a recent book on radiography the author had described the radiology of the accessory nasal sinuses in terms of three positions—the nose-chin position, the nose-forehead position, and the sphenoid position through the open mouth. But Dr. Hodgson pointed out that the first two were no positions at all, because the results would entirely depend upon the facial peculiarities of the individual patient, and a prominent forehead, a long nose, or a receding chin would make all the difference to the way in which the shadows were cast. There could be no standard normal of such a case, and therefore it would be difficult to recognize the abnormal. His own method was to have the patient in the vertical position before the *x*-ray apparatus, the head being lightly fixed in a clamp which permitted of different positions, and to work out a series of six aspects. The first of these was the occipito-frontal position, taking the line from the outer canthus to the external auditory meatus as at a definite angle to the film; the second, the occipito-mental position, in which this line was at an angle of 45 degrees to the film; the third, the vertico-mental, in which the head was tilted back as far as possible; the fourth, the right oblique, in which the head was rotated through 39 degrees; the fifth, the left oblique; and the sixth, the ordinary lateral. Dr. Hodgson showed a series of slides illustrating the normal appearance in each of these positions, and followed them with a number of abnormal cases. The value of the occipito-frontal position, for example, was that the petrous bone was thrown clear above the antrum; of the vertico-mental position, the excellent view of the sphenoidal sinuses which it afforded, and so forth. He indicated, also, how it was possible by a change of position to show whether an abnormality was due to the presence of fluid or to thickened lining of the membrane.

THE PITUITARY

Sir Percy Sargent gave a most entertaining account of the romance of the pituitary gland when he delivered the Harveian Oration on March 19th before the Harveian Society of London. Having introduced his audience to several story-book types and illustrations of mythical giants, he proceeded to show their pathological counterparts. His pictures were variously and widely chosen. From the early conjectures as to the function of the pituitary body in forming the phlegm, he worked up to the recent experiments of P. E. Smith in March, 1930, which have served to confirm the view, put forward by Sir Victor Horsley in 1886, that extirpation of the pituitary body alone, without injury to the adjacent parts, is not inimical to life, although there is cessation of skeletal growth and atrophy of all sexual functions. The lecturer clearly demonstrated that according to the balance of pituitary hormones, giants might be good-looking or ugly, virile or eunuchoid, while hypofunction of the gland gave such syndromes as Simmonds's disease (cachexia hypophysea) and Fröhlich's dystrophia adiposo-genitalis. Nature's crude experiments, however, sometimes made classification difficult, and occasionally types tended to merge into one another. A page from Sir Victor Horsley's notebook (1888), with notes on operative procedure, and containing a plea for early diagnosis, formed an interesting contrast to some recent *x*-ray pictures showing radon seeds in the sella turcica.

[1] *The Significance of the Peking Man.* By Professor G. Elliot Smith, M.D., F.R.S. Henderson Trust Lectures, No. XI. Edinburgh and London: Oliver and Boyd. 1931. (6d.)

The summer session of the West London Hospital Post-Graduate College will open on Wednesday, April 15th, at 4.30 p.m., when an introductory address will be delivered by the dean, Sir Henry Simson, on post-graduate medical education. All medical practitioners are cordially invited.

TOXIC JAUNDICE

LUMLEIAN LECTURES BY SIR WILLIAM WILLCOX

The Lumleian Lectures before the Royal College of Physicians of London were delivered on March 19th, 24th, and 26th by Sir WILLIAM WILLCOX, physician to St. Mary's Hospital, who chose as his subject, "Toxic jaundice."

In his first lecture Sir William Willcox said that the special reason for the selection of his subject had been the frequent occurrence during the last few years of toxic jaundice due to the administration of recently discovered drugs. One of the most important groups of drugs from this point of view was the quinophan group, which included the preparations known as atophan, cinchophen, phenoquin, agotan, atophanyl, and atoquinol, all of them derivatives of quinoline. An interval of several weeks might elapse between the cessation of administration and the onset of toxic jaundice, so that the true cause of the jaundice was often not apparent until careful inquiries had been made as to medicines taken some time previously. This type of jaundice was dangerous; it might terminate in fatal symptoms analogous to those of acute or subacute necrosis of the liver, and he desired to call attention to the dangers of toxic jaundice from commonly used drugs of this type.

DEFINITION AND CLASSIFICATION

The lecturer quoted with approval Osler's definition of jaundice as "a condition characterized by coloration of the skin, mucous membrane, and fluids of the body by the bile pigments." In toxic jaundice, some poisonous factor was at work whereby the excretory power of the liver cells for removing bile from the blood was impaired, and often this same factor caused an excessive destruction of red blood corpuscles with consequent increased production of bile pigments.

The simplest and most satisfactory classification of jaundice was that adopted by Rolleston and McNee: (1) obstructive hepatic jaundice; (2) toxic and infective hepatic jaundice; (3) haemolytic jaundice. No classification could be perfect, as the different varieties of jaundice were often combined. For example, haemolytic jaundice might be combined with toxic jaundice when the toxic agent, such as arseniuretted hydrogen or the toxin of yellow fever, had a destructive action on both the blood and liver cells. The lecturer included under the term "toxic jaundice" all jaundice due to the action of exogenous chemical poisons or of toxins of extraneous or autogenous biological origin, thus comprising all cases in the second and some in the third group, according to the classification given above.

THE FUNCTIONS OF THE LIVER

The part played by the liver in the body metabolism was probably more profound than was at present realized, so complex were the biochemical processes regulated by the liver cells. The bile pigments were produced from haemoglobin by the destruction of red blood corpuscles in the phagocytic cells of the reticulo-endothelial system. It was in these Kupffer cells that the bilirubin was produced, and from them it circulated in the hepatic capillaries and passed into the bile capillaries lying in the centre of the liver tubules. If the liver cells were healthy the bilirubin passed through them and became combined in some loose way with bile salts and cholesterin, but when the liver cells were damaged the bilirubin from the hepatic capillaries could not be fully absorbed by them, and consequently remained in the blood stream.

Normally a certain amount of fat was stored up in the liver cells; this consisted mainly of unsaturated fatty acids in organic combination. In toxic jaundice fatty degeneration was often a marked feature, and the liver cells became engorged with a fat which differed chemically from the normal fat deposits, and was composed of saturated fatty acids in organic combination. Very marked fatty degeneration and distension of the liver cells with fat was met with in toxic jaundice from such chemical poisons as chloroform, phosphorus, alcohol, and trinitrotoluene; it was also seen in the toxic jaundice associated with acute or subacute hepatic necrosis, or with conditions of auto-intoxication, such as acidosis or the toxaemias of pregnancy.

The most important function of the liver was in breaking down the complex products of protein metabolism, many of which had powerful toxic properties, into simple nitrogenous compounds, such as urea and uric acid, which were eliminated by the kidney. When this function was impaired by the action of chemical or biological poisons symptoms of the gravest kind might set in, and death result from the rapidly developing auto-intoxication.

PROTECTIVE ACTION AGAINST EXOGENOUS POISONS

The term "toxiphylactic function" of the liver, indicating its protection of the body against exogenous poisons, had been suggested by the lecturer in a discussion on degenerative diseases of the liver at the Annual Meeting of the British Medical Association in Glasgow in 1922. If a poison was absorbed by the alimentary tract it was conveyed by the portal vein to the liver, which acted as the first line of defence. In the case of poisons introduced into the general circulation, the liver absorbed much of the poison from the blood stream and so protected the other tissues. In exercising this function the liver itself often suffered severely. In fatal cases of mineral or organic poisoning the greater part of the poison was found in the liver. He instanced the Maybrick poisoning case, where the deceased had lived for several days after the administration of arsenic; no arsenic was found in the stomach, and a trace only in the kidneys, while the liver contained 0.3 grain. It was important to remember that in the case of some poisons which were rapidly eliminated the liver might be irreparably damaged and undergo extensive necrosis, so that death resulted several days after the taking of the poison. The terminal symptoms in such cases were due to the endogenous poisons consequent on cessation of liver function, and not to the continued action of the exogenous poisons originally taken. Examples were phosphorus poisoning, delayed chloroform poisoning, and tetrachlorethane poisoning. In such cases no trace of the original chemical poison might be expected to be present in the body at the time of death.

LIVER FUNCTION TESTS

The lecturer then passed in brief review the work done in the attempt to discover a satisfactory test for liver function, analogous to the blood urea test for renal function. At present most of the tests for hepatic function were unsatisfactory in that they failed to indicate the impending danger of that complete breakdown of function which usually terminated fatally in a very few days. The van den Bergh test and the icterus index were of value in indicating the bile-regulating mechanism of the liver, but that was not the function of vital importance. The most valuable test in his experience was the levulose test. The healthy liver could dispose of 50 grams of levulose taken by the mouth without any rise of blood sugar, but if the liver cells were impaired in function a definite rise occurred. The lipase, fibrinogen, and nitrogen partition tests had been found to be of little or no clinical value.

MORBID ANATOMY AND HISTOLOGY

In toxic changes the liver might be greatly enlarged and the section show a striking yellow appearance due to the excessive deposition of fat in the liver cells. This type of liver was to be seen in delayed chloroform poisoning, in the fatal acidosis of children, in phosphorus poisoning where death occurred early, and in some cases of alcoholism. He was informed by the late Sir Norman Moore than the term "cirrhosis" was originally applied to livers showing a marked yellow appearance, and that etymologically this was a correct application of the term, for it was derived from the Greek word "κιρρός," meaning reddish yellow or tawny. Of late years the term "cirrhosis" had become restricted to livers showing fibrotic changes, such as occurred in the portal cirrhosis of alcoholism.

As to the morbid histology, the following changes were seen:

The liver cells commonly showed extensive fatty degeneration and were distended with fat; the cells might be necrosed and granular, their nuclei having disappeared; fibrous tissue might have developed in areas formerly occupied by liver cells; active progressive fibrosis with round-cell infiltration might be present; regeneration of liver cells might occur in the less severe cases; proliferation of the cells of the bile canaliculi might occur in cases less acute.

The lecturer showed drawings of microscopical sections from recent fatal cases of toxic jaundice, and described the cases, which included phosphorus poisoning, cirrhosis of the liver following novarsenobillon injections, alcoholic cirrhosis, and delayed chloroform poisoning.

PATHOLOGY OF TOXIC JAUNDICE

The dominant factor in the causation of clinical effects was the damage to the liver cell. The intensity of the jaundice in any given case was no criterion of the clinical symptoms or of the prognosis. Jaundice might be deep, and recovery yet be complete without dangerous symptoms supervening; or it might be slight, and dangerous symptoms followed by death rapidly develop. In one patient the same poison might exert its toxic influence directly on the liver cells, causing fatal loss of function, while in another it exerted a less severe action on the liver cells, producing changes in the bile ducts and intrahepatic fibrous tissue. The first factor worthy of consideration was the poison itself. Some poisons—for example, phosphorus—exerted a profound and rapid action on the liver. Arsenobenzol derivatives such as salvarsan might occasionally display this intensive action, but, on the other hand, the symptoms from this same group of poisons might be delayed, and deep jaundice result without dangerous clinical symptoms occurring. The intensity of action was so variable in individual cases that the prognosis must always be very guarded.

The second important factor was idiosyncrasy. In some cases lack of nutrition of the liver cells might be an explanation of its occurrence; for example, too prolonged fasting before the anaesthetic might account for the occurrence of delayed chloroform poisoning.

The lecturer mentioned a case of marked idiosyncrasy to an arsenobenzol derivative. There had been a previous history of jaundice in 1915 during paratyphoid fever. In June, 1929, 0.3 gram novarsenobillon was given intravenously, and in July 0.45 gram. Five days after the second injection jaundice developed, but cleared up in a few days. Later in the month 0.1 gram novarsenobillon was given intravenously, followed by a severe attack of toxic jaundice lasting for three weeks, from which the patient eventually recovered.

The time factor was also important. The intensive action of a liver poison for a very short time was likely to cause degenerative changes of the hepatic cells, and clinical symptoms of auto-intoxication accompanied by jaundice of varying intensity would result. Examples of intensive action of a liver poison for a short time were seen in toxic jaundice from chemical poisons, and another example was yellow fever. The action of the poison might, on the other hand, be spaced out, so that the effect on the liver was less acute. A period of mild symptoms of auto-intoxication, commonly diagnosed as toxic gastritis, supervened, and this was followed by toxic jaundice. The lecturer emphasized strongly (1) that when some toxic agent was at work, such as the atophan or arsenobenzol group of drugs, the onset of jaundice might be very long delayed, and (2) that, jaundice having once set in, it might continue for months or years without the existence of any mechanical obstruction of the large bile ducts, the jaundice being due solely to the toxic hepatitis present, which might be progressive. It was important to realize this, because in such cases surgical interference was dangerous and even fatal. In jaundice from quinoline derivatives the onset was often delayed for several weeks after the administration of the last dose of the drug. Toxic jaundice having once set in, the condition might persist for months or years. The lecturer quoted two cases in this connexion.

One of these was the case of a female, aged 30, reported from the clinical medical unit of St. Thomas's Hospital. Death occurred from ascites and subacute necrosis of the liver ten years after jaundice from trinitrotoluene poisoning. The microscopical specimens showed chronic fibrosis of the liver with consequent obstruction to the bile ducts, which accounted for the continued jaundice.

The other case was that of a man, aged 33, seen by him in 1924 and subsequently. There was a history of enteritis from 1916 to 1918. He was in Russia and Mesopotamia during the war. He had small-pox in 1918, and influenza every year from 1918 to 1921. In August, 1923, jaundice developed. There was no history of alcoholic indulgence or syphilis. Wassermann reaction was negative. The liver showed smooth enlargement. The jaundice persisted in varying intensity until death, in October, 1927, symptoms of acute hepatic necrosis developing and terminating fatally in three days.

The lecturer added that he could quote many other similar cases under his personal observation where a long persistent deep jaundice occurred without mechanical obstruction. Lectures II and III will be reported next week.

ROYAL MEDICAL BENEVOLENT FUND

ANNUAL MEETING

The annual general meeting of the Royal Medical Benevolent Fund took place on March 17th under the presidency of Sir THOMAS BARLOW. Sir PERCY SARGENT, joint honorary secretary, in presenting the report for 1930, stated that 661 grants had been voted during the year, amounting to £9,591, an allocation of nearly £1,000 more than in 1929. The grants came under several headings, chiefly maintenance grants to beneficiaries with very small incomes, but also grants for educational fees, for help in sickness, and to meet temporary needs. The annuitants of the Fund now numbered 177; five of these were given pensions of £100, and seven received amounts varying from £40 to £100.

Sir CHARTERS SYMONDS, honorary treasurer, reported that the income from subscriptions and donations had, for the first time, reached five figures, £10,081, an increase of £850 on the previous year. Legacies brought in £12,000, thanks chiefly to the balance of the legacy of Dr. Alexander Lawrence. The number of new subscribers during the past year was 584, of whom 223 came through the British Medical Association. Grateful mention was made of the help of the Association, which, in subscriptions from its members, had collected for the Fund £1,970—an increase of £379 on the year. The Charities Committee had also allocated £1,368, an increase of £372.

Sir Charters Symonds specially mentioned the work of the charities secretaries in the Divisions of the B.M.A., as well as other organizers of social functions for helping the Fund in various localities. Several Divisions had sent handsome donations, two—from Bath and Southport—amounting to over £100, and the distant Malaya Branch had again sent a contribution of £58. Another welcome helper was the Medical Insurance Agency, which had contributed £630 during the year, making a total of £6,954 received from this source during the last twenty years. An appeal was made to Panel Committees, twenty-four of which became new subscribers in 1930.

Sir THOMAS BARLOW said that these two reports were eminently satisfactory. The Fund had made definite progress during the year in securing the support of the profession. The number of applicants dealt with had largely increased, and, at the same time, thanks to additional income, it had been possible to deal with them more liberally. Dr. C. O. HAWTHORNE, Chairman of the Case Committee, gave some account of the procedure of the committee in making grants. A large number of the applications, he said, came from elderly ladies, widows, or daughters of medical men, who had been delicately nurtured, and had lived a sheltered life, until they were suddenly reduced to indigence. While it was probable that in many cases there had been a lack of prudence, not necessarily on the part of the applicant, he thought it would be agreed that the position was not to be met by the severely critical examination of the economist or of the moralist, but by the generous judgement and help of those who were more fortunate.

Mr. R. M. Handfield-Jones, who has served as joint honorary secretary for some years, has found himself compelled to tender his resignation owing to the pressure of other work. The resignation was accepted with much regret, and Dr. Lewis Glover was elected in his place. With this exception, and with certain additions to the list of vice-presidents, and to the committee of management, the officers and committee were re-elected. In moving one of several votes of thanks, Mr. BISHOP HARMAN referred to the extraordinary amount of work, extending over many years, which Sir Charters Symonds had rendered to the Fund. The identification of the Fund and its treasurer was a remarkable example of symbiosis, and, as in other examples of that biological phenomenon, it seemed to have the effect of making Sir Charters appear younger every year.

Scotland

Hospital Services in Scotland

An address on the need for hospital reorganization was delivered by Sir Robert Bolam, under the auspices of the Edinburgh Branch of the British Medical Association, on March 18th in the B.M.A. House at Edinburgh. Dr. G. Keppie Paterson presided over a meeting which was widely attended by practitioners from the south-eastern area of Scotland, and by hospital staffs and officials of the Department of Health for Scotland. Sir Robert pointed out that not more than about 15 per cent. of the patients in large hospitals, such as the Edinburgh Royal Infirmary, belonged to the class of the indigent sick for whom such hospitals had originally been established. Hospital provision for this class of patient was now a statutory duty of local authorities both in England and in Scotland, and whether they were to be treated in a voluntary or a municipal hospital was largely a matter of local arrangement. The great teaching hospitals had nowadays come to provide medical and surgical treatment for the well-to-do artisan and also for a number of persons in more affluent circumstances. Although these people might not be able to pay the sums required for treatment in hospital when an emergency arose, they were well able to do so by means of some contributory or insurance scheme. He quoted the figures for several comprehensive contributory schemes which had already been established among workers in various English centres, such as in the Birmingham district and on Merseyside. These were so thoroughly organized, he said, that they placed the hospitals of their districts in a sound financial position, able to render thoroughly adequate medical services. He was convinced that it would be a misfortune to organize a contributory scheme on the basis of an individual hospital; the scheme should always be drawn up for an area, and the smaller hospitals should thus be brought into correlation with the large central hospital or hospitals of the district. In order to obtain a thoroughly efficient service, it was essential that the members of hospital staffs should be adequately remunerated, and this could readily be done when such contributory schemes as he had in mind were developed. An important point in this connexion was that in some of the larger centres a municipal hospital might be developed side by side with a voluntary hospital. In the former the staff would necessarily be paid; in the latter, if the staff was unpaid, its medical services would inevitably be prejudiced. Referring to the functions of the general practitioner respecting his patients under treatment in the large hospitals, he thought that more adequate means than at present existed should be provided for making information as to diagnosis and treatment available. He considered there would be scope for the work of the general practitioner in the home hospitals, which might come into existence for patients requiring rest and simple methods of treatment without necessary recourse to the consultant or the specialist.

Medical Women's Federation

The South-Eastern Association of the Medical Women's Federation held its annual dinner in Edinburgh on March 13th. Miss Gertrude Herzfeld presided, and in proposing the toast of "The Guests," remarked that this was the first occasion when male guests had been entertained. The question, she said, was sometimes asked why there was a women's hospital, and the answer was because women doctors were not yet admitted to the staff of the Royal Infirmary; when they were, they hoped that a women's hospital, run entirely by women, and a women's federation, would no longer be necessary. Women wished to take their part in the medical profession as a whole, alongside men colleagues. They were trying to do something to make themselves worthy of recognition, and in Edinburgh, spurred on by the example of the Marie Curie Hospital in London, they had decided to take up the gynaecological aspect of radium treatment. Accordingly they had formed a definite system of research, which had gained the recognition of the Medical Research Council. Professor R. W. Johnstone, in proposing the toast of "The Cancer Research Committee of the Scottish Associations of the Medical Women's Federation," said that there was ample room for the work of this committee as well as for that being carried on at the Royal Infirmary, thanks to the generous donation of radium by the Radium Commission.

Mental Hospital Appointment

At a meeting of the Public Health Committee of the Edinburgh Town Council on March 17th, it was resolved to recommend the appointment of Dr. William Malcolm McAlister as medical superintendent of Bangour Asylum, and medical officer in charge of the mental health services of the corporation. This appointment is in succession to Dr. John Keay, who retires on May 15th. Dr. McAlister, who is 42 years of age, is a native of Campbeltown. He graduated M.B. at Edinburgh in 1918, and became a member of the College of Physicians in

1926, proceeding to the Fellowship in 1929. Shortly after graduation he joined the staff of the Royal Mental Hospital at Morningside, and was promoted in 1923 to be deputy physician-superintendent of this institution; in this capacity he has acted as a lecturer in psychiatry in the University of Edinburgh and in the School of the Royal Colleges at Edinburgh.

Scottish Odonto-Chirurgical Society

At the annual meeting of the Odonto-Chirurgical Society of Scotland, held in Edinburgh Dental Hospital on March 13th, Mrs. Lilian Lindsay read a paper on the prevention of dental caries, in which she said that diseased teeth were mentioned in almost all ancient literature, and that no race was entirely immune from dental caries. The article of diet which from time immemorial had been universally blamed as the most destructive to the teeth was sugar. The lecturer considered that whole-meal bread, fruit, and uncooked vegetables were articles of diet least destructive to the teeth. At the annual dinner held on the same evening, Dr. William Guy, dean of the Edinburgh Dental Hospital and School, said that the institution was founded seventy-five years ago when Dr. John Smith began dental education in Edinburgh with a course of lectures on the anatomy and physiology of the teeth. In 1878 the passing of the Dentists Act had stimulated the Royal College of Surgeons to frame a curriculum and institute a diploma in dental surgery. Since then great success had attended the Edinburgh Dental Hospital and School; at present well over one thousand of its former students were on the *Dentists Register*.

England and Wales

Wandsworth Memorial for Tropical Research

On March 13th Sir Frederick Gowland Hopkins, President of the Royal Society, unveiled, in one of the principal laboratories of the London School of Hygiene and Tropical Medicine, a plaque in memory of the late Lord Wandsworth, who left a sum of £10,000 to found a scholarship for the promotion of medical research in one of the London medical schools. The ceremony was performed in the presence of Sir William Hamer and Dr. E. Deller (Principal of the University) and others, during an official inspection of the School by the University of London and in the presence of a large class of students drawn from all parts of the world. In unveiling the tablet, Sir Frederick Hopkins expressed the hope that the work already done and the opportunities for the future which the scholarship afforded would be an abiding source of inspiration.

Schools for Physically Defective Children

The principle of the separation of poor relief from assistance which can be provided under special Acts is particularly applicable to the provision made by local authorities for blind, deaf, defective, and epileptic children, since Part 5 of the Education Act gives local education authorities full power to provide for the maintenance as well as for the education of these children in residential special schools. In Circular 1411 of February 6th, 1931, the medical branch of the Board of Education directs the attention of the appropriate authorities to the desirability of employing these powers in the case of children whose fees at residential special schools would under the former practice have been paid by the Poor Law authorities. The necessary amendments in the Special Service Regulations of the Board of Education have been embodied in draft Grant Regulations, Nos. 3 and 19 (Amendment No. 1 of 1931), which define the grants payable to special schools where the new policy is adopted. The Regulations, which will come into force on April 1st, provide that in schools for physically defective children in which special arrangements are made for medical treatment and care the Board may increase the prescribed grant in respect of each unit of average attendance by a sum not exceeding £4 for a day pupil and £9 for a boarder where the arrangements are held to justify such an increase. Provision is also made for grants in respect of courses of higher education for blind, deaf, defective, or epileptic students.

Extension of London Lock Hospital

An extension of the London Lock Hospital, at Dean Street, Soho, was opened by the Lord Mayor on March 20th. The work at Dean Street, where 90,000 attendances were registered last year, and fifteen clinics are held every week, has suffered from inadequate buildings and restricted site. Thanks to money provided by the trustees of the late Mr. Peter Coats of Paisley, it has been possible to purchase the freehold of the site, and other generous gifts have been made to the extension, including grants from the King's Fund. The new provision, costing £22,379, towards which £17,102 has already been raised, includes large consulting room accommodation, dispensary, intermediate treatment department, and an addition to the pathological and research departments, where the number of tests carried out last year was 16,000. The experiment is also to be made of a ward for paying patients of moderate means, as advocated by Lord Trevethin's committee. After Lord Kinnaird, the chairman of the board, had explained the nature of the extensions, Mr. Charles Gibbs, senior surgeon to the hospital, and chairman of the medical committee, thanked Lord Kinnaird and the board for the beautiful workshop they had built. When the pathological laboratory was completed there would be a perfect unit for the diagnosis and treatment of the special diseases for which the Lock Hospital existed. Hitherto Dean Street had been allocated to male patients, the work at Harrow Road being devoted to women; but it would now be possible to accommodate women out-patients in the new buildings, and new wards were to be built for women and children, including maternity cases, and when the women patients had been rendered non-infective, they would be transferred to a recovery home in the country. Mr. Gibbs also mentioned that roughly one-half of the female patients were women who had been infected in marriage, and were therefore wholly deserving of sympathy. The Lord Mayor, in declaring the building open, said that the Lock Hospital had a record of 184 years' activity, and was the only voluntary hospital specializing in this work. The Lock Hospital offered treatment under somewhat different conditions from those obtaining at the public health clinics, and supplied a need which those clinics did not altogether meet. It was also the only venereal diseases hospital clinic which asked for a contribution from its patients, and thereby it encouraged self-respect.

The North Middlesex Hospital

The cover of the latest report of the North Middlesex Hospital, Edmonton, bears the inscription that the expense of a reprint has been defrayed by a grateful patient. Were this not the case, some misguided ratepayer under the Middlesex County Council (which has now, under the Local Government Act, taken over the supervision of the hospital from the Edmonton board) might object to a report so elaborate being printed, however important the institution. The report includes no fewer than twenty-five closely set tabular pages giving

particulars of all the medical and surgical cases treated and the major operations performed. These tables indicate the extraordinary range and variety of work which a great hospital of this kind has to cover, its area of operation including seventy square miles of Middlesex and Essex. The claim is made that it takes in more patients than all the voluntary hospitals in the whole county of Middlesex. The total admissions for the year under review (including the thousand or more who were admitted by birth in the maternity wards) amounted to 10,443, and the out-patients numbered 26,956. The work of the different departments is briefly reviewed. A year ago the opening by the Minister of Health of the radium and deep-therapy department was reported in this column. It is stated that already some very successful results have been obtained by radium which would have been impossible by operative surgery.

New Houses for Old in St. Pancras

Within a quarter to half a mile north of the British Medical Association House in London, and under the shadow of Euston Station, a ceremonial "burning" of slum property took place lately, General Sir Ian Hamilton lighting the pyre. The ceremony marked a further stage in the operations of the St. Pancras House Improvement Society, of which the Rev. J. B. L. Jellicoe is chairman and organizer. The society, during its six years of existence, has acquired three properties in the Somers Town district of St. Pancras, the latest of these comprising ninety-six houses, and has taken in hand their reconditioning, replacing dilapidated dwellings by pleasant and tidy flats on the same site, and on not too ambitious a scale for the displaced tenants. The estate is sympathetically managed on the lines popularized by Miss Octavia Hill, and the society sponsors welfare work, nursery schools, and other enterprises for the health and well-being of the people. Those who recall some of the dingy purlieus which have been "burned" will rejoice in the transformation, and perhaps will desire further information about this social venture, which can be obtained at the offices of the society, 96, Seymour Street, Euston.

[FROM OUR CORRESPONDENT]

Progress of Obstetrics

At the congress last year known as the "Journées médicales de Bruxelles," Professor Maurice Brouha of Liége, made a striking speech on the present position of obstetrics. After recalling the recent history of obstetrics —the "poverty-stricken parent of surgery and medicine" —Professor Brouha sketched broadly an impressive picture of pregnancy as it is understood to-day—a kind of transitional stage, in the course of which the normal physiological balance is upset in order to give place to an unstable situation created partly by physiological and partly by pathological conditions. Clinical obstetrics, he said, had gained immensely by the discoveries of the laboratory, by the progress of surgery, and by sociological inquiry. Among the most striking of the morbid phenomena of pregnancy was puerperal infection, of which the double origin—exogenous and endogenous—had been clearly established. The possibility of its occurrence imposed the necessity of a most rigid precautionary technique, involving extreme care as regards asepsis and antisepsis, and the development of a surgical outlook by all who wished to become obstetricians in the fullest sense. The chief scope for displaying the obstetrical sense was found in the sphere of pelvic contraction. Whereas in the past the need for prophylactic Caesarean section had been regarded as imperative, and its practice bristled consequently with faults and abuses, there had been brought into being to-day—thanks to the introduction of low Caesarean section—a sound indication which was based upon a practical preliminary test—namely, trial labour. This permitted a considerable reduction in the number of interventions which would otherwise have been considered necessary. The surgical tendency in modern obstetrics was particularly manifest in placenta praevia, a condition which was responsible for the serious maternal mortality of 10 per cent., and destroyed 50 per cent. of the infants. In eclampsia the old practice of hastening delivery through the normal passages was being replaced more and more by expectant medical treatment, and surgical intervention when the life of the infant was at stake. The conclusion from all this was that the obstetrician of to-day must possess very high medical and surgical qualities; these could only be attained by long and patient post-graduate study in a carefully chosen environment.

Instruction in Tuberculosis

The teaching of tuberculosis in Belgium is not a distinct part of the general medical curriculum; in none of the four universities is there a chair of tuberculosis. Theoretical instruction in this subject is given in the four faculties of medicine by the professors of pathology, there being also courses of special microscopical and pathological demonstrations. The professors of public health lecture on the medical and sociological sides of the campaign against tuberculosis, and the professors of bacteriology deal with all that pertains to the laboratory side. Practical instruction is afforded in the university hospitals, or in those controlled by public health organizations in close association with the faculties of medicine. It is obviously desirable that there should be a closer linking up of the university faculties of medicine with the officially recognized anti-tuberculosis associations; in order to achieve this it is proposed to place at the disposal of these faculties a dispensary modelled on the well-known Calmette-Malvoz type. This will be equipped and conducted on the most modern lines.

Medical Finance in the Congo

It has been decided that the home Government shall contribute to the proposed medical fund for financing a crusade against tropical diseases in the Belgian colonies. It will be necessary to enlist in this medical undertaking the services of all those persons and societies in Europe and the Congo who take an active interest in promoting the health of the natives. Such a co-ordination will be brought about by the establishment of a civilian body, including representatives of the Colonial Government and of the principal industries in the Congo, as well as medical experts, missionaries, and representatives of any philanthropic institutions which are likely to be concerned. A financial endowment will be provided in order that support may be given to medical missions operating in the Congo under the control of the Government medical authorities. A sum of 100 million francs has been set apart locally, and the home Government will contribute 50 million.

Industrial Physiology and Pathology

The executive committee of the Free University of Brussels has approved a suggestion made by the faculty of medicine, and will create a special organization to deal with the physiological and pathological aspects of industry. This new body will be charged with the selection of medical officers in industries and the consideration of the various diseases associated with each occupation. Dr. Maurice De Laet has been appointed president of the new body.

Correspondence

SPECIFIC SERUM TREATMENT OF LOBAR PNEUMONIA IN ADULTS

SIR,—I have read with interest the contribution of my friend Dr. R. A. O'Brien to the discussion on the treatment of lobar pneumonia at a recent meeting of the Medical Society of London, as reported in the *Journal* of March 14th. The summary of his comments on the present position of the specific serum treatment of pneumonia makes it appear that he is not satisfied with the clinical evidence which has been presented in its favour, and that he cannot find justification for the use of the serum from experimental work on the subject. The sketch he has drawn of the unstable foundations of the specific treatment of the disease is so deeply overshadowed with scepticism that physicians whose interest has been aroused by recent accounts of the trial of antipneumococcus serum in this country may imagine that there is no rational basis for the serum therapy of pneumonia. I cannot accept this view, and should like to modify the impression which Dr. O'Brien's statement must have made by trying to show that there are many encouraging signs, not only in the clinical records, but in those which give an account of experimental researches into the mode of action of the serum and the methods of titrating it.

The clinical work in the United States has been conducted with notable thoroughness by groups of experienced clinicians, some of whom have added valuable knowledge from their experimental work on pneumococcal infections. In the hospital of the Rockefeller Institute, Cole has tested the serum therapy of pneumonia in a considerable number of cases, and is so convinced of its value that he finds it repugnant to his conscience to withhold the serum from patients whom he thinks it may benefit; he is thus unable to make a comparison with a control series of untreated patients. The lack of statistical proof that the serum is effective does not deprive his experience of evidential value, for the clinical instinct of trained observers deserves due consideration when assessing the efficacy of a therapeutic agent. Both Park and Cecil and their colleagues have made controlled observations in the hospitals in New York on a scale which renders their data suitable for analysis by statistical methods. The results of analyses of this kind indicate that the difference in the mortality rate in favour of the serum-treated cases is a significant one when Type I pneumonia alone is considered; there is general agreement that only Type I infections, and to a lesser degree Type II infections, are influenced by a specific serum. When we reflect that in Great Britain and America strains of the pneumococcus belonging to Types I and II have been found in about 55 per cent. of cases of lobar pneumonia in adults it is apparent that there is no lack of opportunity for testing the therapeutic value of an appropriate serum preparation. Those of us who shrink from the intricacies of statistical analysis will find evidence in the clinical accounts that the treatment mitigates the symptoms. The American observers agree that the serum often lessens the severity of the symptoms so that even within twenty-four hours the temperature, the pulse rate, and the respiratory rate are reduced or have become normal. According to Cecil and Plummer, there is no more striking clinical effect in the whole field of specific therapy than that which frequently follows the early administration of the serum. The temperature falls rapidly, so as to simulate the natural crisis, and the toxaemic symptoms often disappear within twenty-four hours. Moreover, after one or two injections of the serum, pneumococci, when present in moderate numbers in the blood stream, quickly vanish.

Dr. O'Brien is reported to have professed himself dissatisfied with the evidence which relates to the action of the serum in experimental infections; yet it is well known that a specific serum can protect a mouse so that it shows no signs of illness when it is inoculated with a quantity of a fully virulent culture of a Type I pneumococcus which represents, for example, ten million lethal doses. This serum is one of the group of antibacterial serums, and yields more convincing experimental proof of its efficacy than any other serum of its kind with which I am acquainted. Moreover, the researches of Griffith and of the workers in the Rockefeller Institute on virulent and avirulent variants of the pneumococcus (the "rough" and "smooth" variants of Arkwright), and those of Avery and Heidelberger on the type-specific polysaccharides and their relation to the antigenic properties of the pneumococcus, have illuminated the mechanism of infection and the mode of action of type-specific pneumococcal serums to an extent which has no parallel in immunology at the present time. It is true that there are difficulties in the titration of Type I and Type II serums which have not yet been overcome, but Dr. O'Brien's colleagues have furnished evidence that it is possible to test serums of this kind with a fair degree of accuracy, and work that has been carried out in this laboratory has brought us to the same conclusion. There is no reason to doubt that in due course a satisfactory method of titration will be discovered, and that it will become a routine procedure in serum laboratories.

Time is a powerful solvent of technical difficulties, and since most of the important work on the serum therapy of pneumonia has been accomplished during the past decade, it is natural to believe that progress will continue to be made, both in the laboratory and in the hospitals. The conclusion seems to be justified that the specific serum therapy of lobar pneumonia rests upon a structure of carefully controlled clinical evidence which is strongly supported on the experimental side, and that physicians who use the serum may do so with some assurance that they are employing a logical method of treatment.—I am, etc.,

Lister Institute, Elstree, March 21st. G. F. PETRIE.

SIR,—Dr. Petrie kindly sent me a copy of his letter; I am indebted to him for the opportunity—with your permission—of making clear some points which had become obscured in your report owing to condensation, and doubtless to my lack of clarity in the discussion. I am as deeply appreciative of the enviable achievement of the New York teams of workers as I am grateful to several members—in particular, Drs. Avery, Bullowa, Cecil, Felton, and Park—for full information on many occasions of the progress of the work, and for their inexhaustible patience and kindness in supplying samples of serum and cultures, and any depreciation of their work was far from my intention. While trying to emphasize that, after studying the American statistics and the two recent reports from Edinburgh and Glasgow, I felt it one's imperative clinical duty to give antipneumococcal serum in pneumonia (at least that caused by Type I pneumococcus), I asked that we should keep our minds open to the extreme difficulty in clinical medicine of providing evidence and drawing deductions that will stand the test of time. Lord Dawson, in his able review, had expressed almost the same point of view: "Results . . . are encouraging, though not yet conclusive."

Dr. Petrie concluded from your report that I was dissatisfied with the results of laboratory researches in this field, and justly remonstrates. But, on the contrary, I

pointed out—or attempted to—that after a large amount of work by my colleagues here during the past two years, we were satisfied that we could titrate antibody Type I with satisfactory accuracy, that the Felton and Banzhaf methods, in our experience, do materially concentrate the antibody, so that we have prepared stocks of serum, now in clinical use, equal in antibody content (Type I) to the most potent serum Dr. Felton kindly sent me, and that I was so deeply impressed in the laboratory by the remarkably high power of antiserum to protect mice that I was disappointed that the reduction in the death rate in pneumonia following the use of serum was not more dramatic. I doubted whether in England we could obtain sufficient clinical material with proper laboratory control —particularly typing and blood culture—to make any significant statistical contribution to the subject. What was also in my mind was whether it may not be possible —assuming that one can produce in the dog or monkey a condition comparable with lobar pneumonia—to work out under controlled laboratory conditions, in parallel with clinical research on the New York scale, when and how best to use serum.—I am, etc.,

R. A. O'BRIEN.

Wellcome Physiological Research Laboratories,
Beckenham, March 23rd.

TREATMENT OF GASTRIC AND DUODENAL ULCER

SIR,—Mr. Rendle Short's statistical inquiry into the treatment of gastric and duodenal ulcer should help to clear up the present chaotic state of opinion upon this subject. Although the statistical method of approach, owing to the lack of necessary standards of description, is open to many fallacies and, in my opinion, leads to conclusions far less valuable than those expressed by an individual first-hand student of the subject, at present it is the only method which enables us to sum up a large mass of evidence obtained from widespread sources. Within the limitations of the method Mr. Short appears to have done this in a very fair and unbiased fashion. His conclusions therefore deserve serious consideration, and although I find myself unable to agree with many of them, I feel sure that they may be said to represent the standpoint of the majority of English surgeons to-day.

I was particularly pleased to notice that he again called attention to the "serious fallacy" of judging cure by radiographic appearances, a mistake which we are all at times apt to make. On several occasions I have operated upon patients in whom there was obvious radiographic evidence that a large ulcer had been "cured," only to find an extensive ulcer still present. In a previous communication I pointed out that submucous oedema and muscular spasm may increase the radiographic size of a crater manyfold, and under treatment with appropriate serums I have seen such an ulcer "disappear" radiographically in much less time than even the most enthusiastic physician would be inclined to claim. An ulcer drawn up to the radiographic "skyline" of the lesser curvature by inflammatory induration of the gastro-hepatic omentum may again become posterior, and so partly hidden radiographically, with the subsidence of that inflammation, without any real change in its size. These are but a few of the ways in which the *x* rays can deceive unless constantly controlled by operative findings.

It is unfortunately not clear from the earlier part of Mr Short's article whether he now considers that haematemesis can be a sign of a "tiny withered-up appendix," but if so, I should join issue with him. It may well be that no ulceration was demonstrated in these cases, but the surgeon whose practice includes a considerable percentage of gastrectomies, or who uses endoscopic methods for the detection of lesions, knows only too well how easily small gastric ulcers without surrounding induration can hide themselves under the fat of the gastro-hepatic omentum, or duodenal ulcers on the postero-internal aspects of that structure. One may have reasonable doubts, therefore, whether more complete examination in the recorded cases would not have revealed such ulceration associated with the appendicular condition.—I am, etc.,

London, W., March 15th. NORMAN C. LAKE.

SIR,—In the *Journal* of March 14th (p. 435) there appears a comprehensive survey of the treatment of gastric and duodenal ulcer by Mr. A. Rendle Short. Considering as he does both the medical and surgical aspects of this vexed question from the statistical aspect, he has done much to clarify the situation and to promote a better understanding of the factors involved in peptic ulcer. In an attempt, however, to make his survey as international as possible, the author has fallen into error. He states:

"The large proportion of poor end-results, and certain theoretical considerations, have led most of the prominent American and Continental surgeons, and some British, to advocate big resection operations for both gastric and duodenal ulcers."

It is certainly true that in most Continental clinics, with the exception of a few such as that of Gosset, extensive resections for duodenal ulcer are performed as a routine. That most prominent American surgeons follow the same custom is, however, quite incorrect. Possibly the author was misled by an unfortunate choice of literature dealing with this point, or he was impressed by the apparent weight and number of the publications emanating from those few surgeons who would, and do, sacrifice three-quarters of an otherwise normal stomach upon the altar of a pin-point ulcer of the duodenum. On the contrary, the majority of American surgeons, both in Canada and in the United States, are exceedingly conservative in the surgical treatment of benign gastric and duodenal ulcer, and in their growing preference for direct operations on the duodenum and pyloric sphincter in selected cases are even more conservative than many British surgeons. Nevertheless, the popularity of these lesser procedures does not alter the fact that gastro-enterostomy remains the sheet anchor of surgical treatment of duodenal ulcers throughout the United States. This view was well expressed at the symposium on gastric disease held a few months ago in New York, and participated in by such prominent surgeons as Deaver, Horsley, Gatewood, Gibbons, Douglas, Hartwell, Felter, Finney Hanrahan, Bevan, Balfour, Judd, and W. J. Mayo. The proceedings appear in *Annals of Surgery* (1930, vol. xcii). In many respects the procedures, end-results, and mortality compare with those published in the collective report of the British Medical Association. The poor results and high incidence of recurrent ulcers reported by Berg and Lewisohn of New York are certainly not representative of the country at large, and have not been accepted in any of the more prominent surgical clinics. It should be remembered, however, that the clinical material of this school is drawn from hospitals with a clientele predominantly Jewish, a race in which the management of gastric disease is notoriously difficult.

May I add a few observations frequently made by my former teachers D. C. Balfour and C. H. Mayo? Balfour always insisted that no operation will give perfect results in such a chronic disease as peptic ulcer, and the attempt to establish one operation to suit all types is doomed to failure. Recurrent ulcer may, and occasionally does,

llow any type of operation, including partial gastrec-
my. Provided, however, the patient with an ulcer has
rned his gastro-enterostomy by the very adequacy of
is symptoms, no operation in surgery is attended with
ich perfect results in so high a proportion of cases.
layo often remarked that any surgeon who wished to
sect his stomach for a duodenal ulcer would need to run
ster than he could!—I am, etc.,

London, W., March 17th. A. H. McINDOE.

SIR,—It does not seem right that Mr. Rendle Short's tatistical inquiry into the treatment of gastric and uodenal ulcer, published in the *British Medical Journal* f March 14th, should pass without comment.

In Table IV he gives the death rate following the performance of gastro-jejunostomy in many countries, and t is gratifying to note that English surgeons can show he lowest mortality. But why does he not quote the best of the English results? Lord Moynihan has reported a series of 500 cases without a death. Mr. Short must know of this series, because he cites other figures for another purpose from the same paper in which it appears. I think he must have omitted it as being too excellent to be representative; but this is not a sound position. If we are to compare British work with foreign let us have the best in each case. As a matter of fact, mere figures give a distorted view. Gastro-jejunostomy in itself is a simple and easy operation, and it is impossible to believe that a death rate of 17.5 per cent. is representative of the best German surgery. The mortality of perforated duodenal ulcers in Leeds is considerably less. There must be factors of which figures alone give no indication. I can mention a very important one—namely, pre-operative treatment. The surgeon who spends days or weeks, if necessary, in preparing his patients for operation is certain to have a lower mortality than one who gives little or no consideration to these details. In other words, it is the condition of the patient which makes all the difference to the mortality of gastro-jejunostomy, and such figures as Mr. Short quotes give no information in this respect.

Many of the above remarks apply to gastrectomy for gastric ulcer, but here another uncertain quantity is added—namely, the kind of ulcer for which gastrectomy is done. If the operation is performed for every kind of chronic gastric ulcer the mortality is certain to be less than if it is reserved for those which erode deeply into the pancreas or liver, and are thereby firmly fixed. I am sure there are many who agree with me that the good functional results and low mortality of gastrectomy are not sufficient reasons for removing two-thirds or more of so important an organ as the stomach when the ulcer is small and easily excisable. It seems unreasonable to suppose that the suture line after adequate excision cannot heal as easily and efficiently as the much larger operative wound inflicted on the stomach by gastrectomy, provided effective and prolonged medical treatment forms a part of the post-operative procedure. Indeed, the simpler operations which have been discarded in the past owing to recurrence of ulceration need to be seriously reconsidered in the light of modern medical treatment.

This brings me to a third criticism of Mr. Short's figures—namely, those concerned with after-results. We often hear, in connexion with operations on the stomach, statements given, almost boastingly, that the patient at the end of two or three weeks was eating anything. Could anything be more physiologically unsound? As it takes at least eight weeks to get a perfectly healed suture line after gastro-jejunostomy done on normal animals, it will surely take much longer for a stomach to recover after years of derangement, and I have no doubt that the surgeon who treats his patients on sound medical lines for many months after operation will show better results than one who does not do so. Mr. Short's figures give no indication as to whether this was or was not done. To reduce such matters intelligently to figures would be most difficult, and yet without such data a very distorted picture is obtained. Statistical inquiries in pure mathematics, where the data are more or less accurately obtainable and applicable, can be expected to give useful information; but in surgical affairs, when many of the data cannot be reduced to such mathematical shape, and especially when many of the obtainable data are not included, statistical inquiries are apt to be misleading.—I am, etc.,

Leeds, March 17th. E. R. FLINT.

THE INCISION IN APPENDICECTOMY

SIR,—Mr. A. Ernest Sawday, in the *Journal* of March 14th, draws attention to the transverse incision of the late G. G. Davis of Philadelphia. As was to be expected, it has given Mr. Sawday good results. I am familiar with Davis's method, as I have employed, during the last twenty years or so, an incision based on that method. The details of my operation were communicated to the Annual Meeting of the British Medical Association at Aberdeen in 1914 (*Journal*, 1914, ii, 459), and I have since employed it, with slight modifications, in all cases of operation in children and adults undertaken directly for appendicectomy. The steps vary somewhat from Mr. Sawday's operation, and are briefly as follows:

A skin incision from middle line outwards to just short of the anterior superior spine exposes the aponeurotic layer. The anterior rectus sheath is then opened about one inch out from the linea alba and the incision carried outwards through the external oblique aponeurosis. The outer edge of the rectus, along with the eleventh intercostal nerve if visible, is elevated from the posterior sheath. The latter, with underlying peritoneum, is incised horizontally, care being taken to keep lateral to the deep epigastric vessels. As the posterior sheath incision is usually insufficient for good access, it is prolonged outwards as far as required between the fibres of the internal oblique and transversalis muscles and through the transversalis fascia and peritoneum. During the operation the rectus is kept retracted inwards by an assistant. The wound is closed in layers, beginning with the inner end of the posterior sheath incision. Interrupted sutures then coapt the fibres of the transversalis, and the internal oblique is treated likewise. The anterior sheath of the rectus is then closed by a continuous stitch, the outer part of which brings together the gaping external oblique aponeurosis. If drainage be required the tube and gauze emerge between the fibres of the transversalis and internal oblique muscles.

The access to the appendix, even when the latter is retrocolic or in the pelvis, is excellent. The late results, with regard to strong scar and absence of hernia, leave nothing to be desired. Davis's original paper will be found in the *Annals of Surgery* (1906, xliii, 106).—I am, etc.,

Glasgow, C.3, March 16th. G. H. EDINGTON.

SERUM ANAPHYLAXIS

SIR,—It is with some surprise that I read in the *Journal* of March 21st (p. 516) the statement quoted by Dr. Brindle from Choyce's *System of Surgery*, for it is hardly in accordance with the facts. An attack of serum sickness with severe anaphylactic symptoms may follow a secondary injection of serum given after the expiration of the latent (or incubation) period, whether the primary treatment by serum consists of a single injection or of a series of injections, a fact to which I drew attention in an address

on serum sickness, published in the *Lancet* of March 2nd, 1918. Cases such as those described in the memorandum in the *British Medical Journal* of February 7th were recorded as far back as 1898 (see Appendix III of the Clinical Society's Report of the Committee on the Anti-toxin of Diphtheria, 1898).

May I draw attention to the use of the word "anaphylaxis" in connexion with serum sickness? I have noticed that in accounts of cases which have been recorded from time to time in various periodicals the word is employed almost entirely to denote a serious condition (rigors, collapse, dyspnoea, etc.). But, as a matter of fact, the anaphylactic or supersensitive state may be shown by symptoms varying from a slight local erythema up to the serious ones mentioned above. That they are anaphylactic, however mild they may be, is revealed by the fact that their latent period is much shortened. Most of the severe cases occur within twelve hours of the secondary injection (von Pirquet's and Schick's "immediate reaction"). Of seventeen cases of this reaction recorded in a paper on the supersensitization of persons by horse serum, published in the *Journal of Hygiene* for July, 1907, only eight or nine could be considered as severe.—I am, etc.,

Hemingford Abbots, March 21st. E. W. GOODALL.

DISSEMINATED SCLEROSIS RESEARCH

SIR,—In your issue of March 14th the Halley Stewart Trust sets out its reasons for establishing, under the direction of Miss K. Chevassut, a new centre for the study of this disease. I am concerned only with that paragraph of the letter numbered 1, in which my name is mentioned. In her original paper in the *Lancet* Miss Chevassut adequately acknowledged such help as I gave her. The Halley Stewart Trustees, however, have mentioned my assistance in terms which might well suggest that I have taken an active part in Miss Chevassut's work. I desire to state that there is no foundation whatever for such a suggestion. Such help and information as I have given to Miss Chevassut has been confined to microscopical methods, and to the use of an appliance devised for my own work on various viruses. Miss Chevassut has not, in any real sense, been "trained" by me. I have simply given to her such help and advice, on matters within my own competence, as I have given to many others in similar circumstances. If any comparison is permissible, my association with Dr. Carmichael's work in this field has been closer and more regular; it was carried out in large part at the National Institute for Medical Research, where my own work is done, and later at the National Hospital, Queen Square, where I visited him at regular, prearranged times.

I have received many inquiries concerning Miss Chevassut's work, which reveal an inclination to associate my name with it. I trust that this disclaimer will make it clear that I am neither entitled to claim credit nor prepared to accept responsibility in connexion with it.—I am, etc.,

London, March 18th. J. E. BARNARD.

OPERATION FOR HALLUX VALGUS

SIR,—An interesting feature of Mr. Roth's article on the operation for hallux valgus is the fact that, contrary to textbook teaching, no bursa or fascia is placed between the two bones. The reason for the interpolation of such tissue is to prevent ankylosis, but if the base of the first phalanx is untouched and its articular cartilage preserved there is no likelihood of interosseous union. The implanting of soft tissue into this narrow articular space is an unnecessary complication of the operation, for a good movable joint is obtained without it.

The deformity of itself frequently does not call for intervention. A patient may have a severe deviation of the great toe and yet be perfectly comfortable. On the other hand, there may be little or no deformity but much misery, and this type is usually associated with osteo-arthritis of the joint, the upper half of the metatarsal head exhibiting erosion of the cartilage and possibly eburnation. The operation therefore resolves itself into a reconstruction of the joint. Most surgeons, I imagine, would avoid cutting through the bursa by adopting a curved skin incision. In removing bone very little need be sacrificed, as Mr. Roth points out; it is enough to cut through at the posterior limit of the cartilage or even not so far back as this. A narrow-bladed saw produces a clean-cut surface in the bone without crushing or splitting the shaft. This leaves the metatarsal with a square end; but to complete the reconstruction, the edges and corners are best pared off with a cutting forceps and then rounded with a file so as to produce a perfectly smooth convex surface to articulate with the concave base of the first phalanx. Failure to reproduce a new joint with surfaces resembling the natural joint is the commonest cause of post-operative discomfort, and hence the disrepute in which the operation is held by many in the profession. If a reconstruction is properly carried out a comfortable movable joint should be the invariable result. It is the operation itself that is all-important, for there is little after-care needed beyond the encouraging of the patient to move the toe actively and passively after the stitches have been removed. Once the wound is healed the patient should be allowed up wearing a bedroom shoe; gradually more substantial footwear is worn.—I am, etc.,

London, W.1, March 16th. A. ROCYN JONES.

SIR,—Mr. P. B. Roth's interesting note on operative technique for hallux valgus induces me to write a few words in commendation of an operation which, in the hands of my surgical colleagues at Bradford Infirmary, as well as in my personal experience, has given results even more satisfactory than operations such as that described by Mr. Roth.

Very briefly the operation I suggest consists in the removal by bone-cutting forceps of the proximal half of the proximal phalanx of the great toe and of the outcrop of bone on the mesial side of the head of the metatarsal bone. Removal of the head of the first metatarsal bone inevitably lessens the stability of the foot; removal of not less than one-half of the proximal phalanx is followed by a functional result as good from the point of view of a movable joint, and quite definitely better as regards capacity for walking and standing.

I have in my own household an example of each of the two types of operation, and there can be no question as to which has given the more satisfactory functional result. I am confident that no one who adopts the operation suggested—for any of the arthritic lesions of the first metatarso-phalangeal joint—will be likely to abandon it for the type of operation in which the articular head of the metatarsal bone is removed.—I am, etc.,

Bradford, March 20th. JAMES PHILLIPS.

SIR,—Early in 1916 the majority of patients admitted to the special military orthopaedic hospital at Shepherd's Bush were young men who had already had an operation performed for hallux valgus or hallux rigidus on the lines
sted by Mr. Paul Bernard Roth. It was then clear that although the operation was relatively satisfactory for

civil life, it did not leave a reasonable proportion of the men fit for long marching. The reason for this was that they had been deprived of a very important support of the foot—the first metatarsal head. Simple operative treatment, which avoided boot pressure on prominent bone without loss of the weight-bearing surface of the first metatarsal head, was then adopted as a routine, with uniform success. The period of convalescence after operation was ten to fourteen days. Similar results are the constant experience in civil practice: the foot is not weakened, and pain is entirely relieved. During the last ten years I have only once removed the head of the first metatarsal—the lady was delighted with the operation because pain was relieved, the pain having been due to boot pressure on prominent bone. She now seeks my advice, however, for relief of pain resulting from undue pressure on the head of the second metatarsal bone—a very common sequel of this operation.

I make this communication because there is a real risk of surgeons with less experience and judgement carrying out the operation described. It is, I believe, fundamentally unsound, and unnecessary for relief of pain, which is the patient's complaint.—I am, etc.,

Birmingham, March 19th. NAUGHTON DUNN.

AN UNUSUAL MENTAL ABNORMALITY

SIR,—Dr. William Brown has done well to point out the occurrence of the "tying-up game," but I think he is wrong in calling it a rare form of perversion. I have sometimes heard schoolmasters say they noticed it among their boys, and have often discovered evidence of such tendencies in the earlier history of those who develop abnormalities in their sexual life. I recollect a patient saying that practically as a baby he had delighted in any form of physical restraint, such as even the tying together of two fingers. Tying up is also part of the rite of flagellation, which appears particularly prevalent in these days.

One must be careful of tracing such abnormalities to a common cause, but I have often thought that masochistic traits appear chiefly in those who in late infancy and in boyhood have been spared any sort of physical punishment, with the result that its infliction is invested with imaginary terrors and humiliation. Whereas the normal boy takes such punishment as it comes (and in later life is somewhat proud of it!), his more sensitive fellow may dwell upon it as an exciting yet fearful ordeal, the thrill of which, but not the pain, he enjoys in such fantasies as the "tying-up game." Later, such boys, probably neurotic, tend to import the thrill of early fantasies into the fantasies of sexual life.

If such an interpretation of the phenomena is justified, its indication for teachers and parents is obvious enough.—I am, etc.,

London, W., March 23rd. G. LAUGHTON SCOTT.

GONOCOCCAL RHINITIS

SIR,—The article by Drs. Kirkland and Storer in the *Journal* of February 14th interested me greatly, and in view of the correspondence which it has evoked I think the details of the following case might be of value, though I know that similar cases have already been described by paediatricians.

An illegitimate child, aged 5 weeks, was admitted to Dundee Royal Infirmary with a history of three or four days' swelling of the hands and feet, no diagnosis having been made. There was oedema of the hands to above the wrists and of the feet to above the ankles, with an obvious inflammatory basis and marked tenderness. A copious bilateral purulent nasal discharge was present, as also was an extensive stomatitis, which at first sight looked typically aphthous. Examination of smears from nose and mouth revealed in a very mixed flora a large number of intracellular diplococci, having the morphology and staining characteristics of the gonococcus. Knowing the difficulty of endeavouring to grow a delicate organism like the gonococcus from the midst of other hardier organisms, no attempt at cultivation was made, but the serum was examined and gave a positive gonococcal complement-fixation reaction. The rhinitis and stomatitis very quickly responded to local treatment, and in the meantime the oedema had gone down, revealing swelling of both wrist- and ankle-joints as well as of several of the small joints of the hands and feet. After some difficulty a little slightly turbid fluid was obtained by aspiration from one of the wrist-joints, and this, too, contained a fair number of Gram-negative bean-shaped intracellular diplococci. The right knee subsequently became involved. Despite the fact that there was no general reaction, and that none of the joints ever became acute, the infant went rapidly downhill. Immediate improvement followed the institution of a course of vaccine therapy with a non-autogenous vaccine, and the child was ultimately discharged well, with no disability in any of the affected joints. The mother would not admit the presence of a vaginal discharge, and steadfastly refused examination.

In the above case the diagnosis appears to be complete; and while that in the case of Drs. Kirkland and Storer seems open to criticism, there is apparently strong circumstantial evidence in its favour. Not being a bacteriologist, I would like to ask Drs. Assinder and Price whether attempts at cultivation of the gonococcus from nasal pus are likely to be successful.

I have to thank Dr. J. S. Y. Rogers, D.S.O., for permission to record the details of this case.—I am, etc.,

Glenlomond, by Kinross, March 6th. A. SCOTT, M.B.

THE ELECTROCARDIOGRAM

SIR,—As a practising cardiologist I consider it my duty to the medical profession to contradict the sweeping assertions of the writer of your leading article on the electrocardiogram in the *Journal* of March 7th (p. 407).

In it he states that the English school holds that the electrocardiogram is only of use in identifying the more difficult forms of irregular heart action, for which it remains as a little-needed final court of appeal, and that its sphere of usefulness is almost confined to the laboratory for the elucidation of academic problems of nerve and muscle physiology. The other school, which he styles the American, he condemns as vociferous and ultra-enthusiastic, in that they have found the electrocardiograph of practical help in determining the state of the myocardium in regularly beating hearts.

The writer bases his statements on the Medical Research Council's Report No. 147 by Dr. W. H. Craib. I have read the report, but do not find anything in it which tends to support the writer's assertions. He concludes, however, by stating that Dr. Craib's report is the deathknell to any extension of electrocardiographic methods to the routine study of the myocardium. With these assertions I am in entire disagreement. There are many serious myocardial affections with a regularly beating heart, the diagnosis of which is absolutely dependent on the electrocardiogram, and for whose treatment a correct diagnosis is of the utmost importance.

Bundle-branch block is an extremely serious heart condition. It is frequently found in patients with a normal heart rhythm. Clinically there are often no gross signs of myocardial damage. The patient's symptoms are often more marked than can be gauged from the clinical findings, and without an electrocardiographic record, which gives a typical picture of the lesion, it is impossible to

say whether there is present a serious heart condition or not. Willius of the Mayo Clinic, who has had abundant opportunity of investigating electrocardiograms of all kinds of heart conditions, in his book on *Clinical Electrocardiography*, published in 1929, gives a mortality of 66 per cent. in twelve months for bundle lesion cases. Yet the writer considers the use of the electrocardiograph purely academic. Partial heart-block is often found with normal rhythm. Delayed conductivity between the auricles and ventricles is impossible to diagnose by clinical means. Two to one heart-block can be suspected in some cases from the slow rate, but cannot be diagnosed with any certainty without instrumental methods. Heart-block, even with a regular rhythm, is of serious import to the patient.

Auricular flutter is not uncommonly present with a normal heart rhythm and without any gross clinical evidence of disease, though the patient's symptoms may be marked. It is usually far from easy to diagnose the condition visually from the altered jugular pulsations, and anyone who has used the electrocardiograph and the polygraph can have no two opinions on the simplicity and precision of the former instrument. The recent work on coronary thrombosis is another instance of the value of electrocardiography in normal rhythms. The fact that cases of coronary thrombosis have been found with normal electrocardiograms does not in my opinion mitigate its great value in the diagnosis of this condition. Paroxysmal tachycardias are not infrequently seen. The exciting focus may be any spot away from the sino-auricular node. The prognosis depends to a large extent on the site of the ectopic focus. Thus paroxysmal tachycardia of ventricular origin is usually more serious than paroxysmal auricular tachycardia. The electrocardiogram offers the only means of sure diagnosis, and is of great help in the treatment. Low-voltage curves are frequently found in elderly subjects, who are prone to anginal and syncopal attacks, and must be considered of some significance.

Willius collected numerous electrocardiograms in which the T-waves were negative in various leads, and gives the following mortality figures:

Negative T i: 67 per cent. mortality in 17 months.
Negative T i, T ii: 65 per cent. mortality in 12 months.
Negative T i, T ii, T iii: 66 per cent. mortality in 12 months.
Negative T ii, T iii: 50 per cent. mortality in 24 months.

Do these figures mean anything to the reviewer? I could instance many other examples in which the electrocardiograph has proved its value in the exact elucidation of myocardial disease, but these examples should suffice. —I am, etc.,

JENNER HOSKIN,
Cardiological Department,
Royal Free Hospital.

March 20th.

MEDICINAL TREATMENT OF CHRONIC ARTHRITIS

SIR,—I read with much pleasure the article on the medicinal treatment of chronic arthritis by Dr. N. Mutch, which appeared in your issue of March 7th. As a practitioner I am indebted to him for his classification of the welter of remedies extant for use in chronic arthritis, and for the careful way that he has explained their mode of action. I have found intramuscular injection of contramine most generally useful, but patients must be warned to expect a severe exacerbation of their pain to begin with. I congratulate Dr. Mutch on the way he has dealt with such a complex problem —I am, etc.,

D. M. MARR, O.B.E., M.D.

Grantown-on-Spey, March 18th.

CONVULSIONS DURING SURGICAL ANAESTHESIA

SIR,—The article on convulsions during surgical anaesthesia in the *Journal* of March 14th (p. 440) is very interesting. May I suggest that one of the toxaemic factors was probably ketosis? All the patients were children, acutely ill with high fever and sepsis. The author does not mention acetonuria, but doubtless it was present. Neither does he state whether glucose was given before operation. All the operations were urgent, and it may have been omitted.

It would be interesting to learn what is the ideal dose of glucose to give children before operation.—I am, etc.,

LOUISE FRASER.

Inverness, March 14th.

PENTAPHARMACUM OR PENTAPERMATUM?

SIR,—In my book *Caesarean Section* I have dealt with Aelius Verus and his Pentapharmacum. His full title was Lucius Ceionius Commodus Verus Aelius Caesar, and he was the first commoner to bear the last-mentioned name. His Tetrapharmacum (more accurately Pentapharmacum) consisted of a sow's udder, pheasant, peacock, crusted gammon, and wild boar (sumen, fasianum, pavonem, pernam crustulatam et apruquam). The perna crustulata appears to be gammon with the crackling so beloved of Elia. To-day, under the heading "An Imperial Roman Game Pie," the *Times*, in a Reuter telegram from Budapest, dated March 20th, gives the recipe for Aelius Verus's Pentapermatum, which has come to light. Is not this the Pentapharmacum with some of the pie changed, and notably by the substitution of ox tongue for peacock? I beg, Sir, that you will endeavour to obtain the Latin text. Though the pheasant and peacock would be a little out of season, the celebrated gourmet's Pentapharmacum would be a fine *pièce de résistance* for the Association's centenary banquet in 1932.—I am, etc.,

HERBERT R. SPENCER.

London, W., March 21st.

CLOSED DRAINAGE IN TREATMENT OF EMPYEMA

SIR,—I read with much pleasure a letter in the *Journal* of March 21st from Dr. William Mitchell ascribing the credit for closed drainage of empyemata to Dr. George Robertson of Oldham. Dr. Robertson published his method in the *Medical Chronicle* as long ago as 1887, together with a series of over one hundred cases in which the average time of healing, with full lung expansion, was only nineteen days. My father, Dr. Frank Radcliffe, succeeded Dr. Robertson at the Oldham Royal Infirmary, and has continued to treat empyemata by Robertson's method, with equally good results.

Robertson's apparatus is simpler than McEachern's. He employed it always after rib resection, as only by manual clearing of the chest is it possible to get rid of the clotted pus in pneumococcal cases. He inserted two tubes side by side, not through the original incision, but through stab wounds. One tube he used for irrigation, and the other drained through "U" tubes into a bottle of weak perchloride solution. Should one tube become blocked it is easy to reverse the circulation. No negative pressure is applied, for, as he shows in his paper, the lung tends to expand with the patient's cough.

Old as they are, Robertson's papers well repay study, and I feel that Dr. Mitchell has done Robertson a great service in drawing attention to his pioneer work in such an important branch of surgery.—I am, etc.,

WALTER RADCLIFFE.

East Suffolk Hospital, Ipswich, March 21st.

Obituary

ARTHUR PERIGAL, M.D., C.M.

New Barnet

Dr. ARTHUR PERIGAL, born in Edinburgh in 1848, was educated at the Edinburgh Academy and University, graduating M.B., C.M. in 1869, with his life-long friends Byrom Bramwell and the late James Dunsmure. He was house-surgeon to Spence and house-physician to Hughes Bennett before going to Vienna, where he met the late Robert Farquharson and Herbert Page, with whom he became an intimate friend; later he was in Rome, where he wrote his M.D. thesis on Roman fever. He started private practice at Wheatley with Dr. Stovin, eventually joining Dr. Livingstone at New Barnet in 1878. During fifty years of practice there his handsome and genial presence and untiring energy endeared him to all, setting a lasting example of conscientiousness and unselfishness. He was a member of the Royal Medical and Obstetrical Societies of Edinburgh and London, and an early member, and latterly a vice-president, of the Edinburgh University Club of London, in which he took a lively interest. He leaves two married daughters, and a son who has been in practice with him for over twenty-five years.

Mr. C. W. MANSELL MOULLIN writes:

There are very few people in New Barnet and the neighbourhood for many miles round who will not deeply regret the loss of one of the kindest friends they can ever have known. Dr. Perigal had been in practice for upwards of fifty years, and was esteemed and respected by everyone. Old and young alike believed in him, and trusted him. He had a wonderful power of inspiring confidence, was never hasty in making a diagnosis, and while keeping an open mind was thoroughly conversant with all the latest advances. Since the death of his wife a few years ago he had withdrawn more or less from active work; but the experience he had gained through so many years was always at the service of those who sought it, and it rarely failed to bring relief. He never looked upon patients as cases, but as men and women, suffering from pain and disease, in need of sympathy, and they became his friends.

Dr. ALDREN TURNER writes:

By the death of Dr. Perigal, at the age of 82 years, there has passed away one of the few remaining graduates of Edinburgh University who commenced their anatomical studies under Goodsir. After spending some time abroad he settled down in general practice, and for over fifty years was the outstanding figure in the medical life of New Barnet and district. He had all those qualifications which make for success in our profession: a handsome presence, a strong and energetic personality, the power of inspiring confidence, and an assured and well-balanced judgement. He inherited the artistic gifts of his family, his father having been a Scottish academician, and a painter of repute in his day.

JAMES LAURIE, M.B., C.M.,

Consulting Surgeon, Greenock Royal Infirmary

The death took place on March 12th, in his seventy-first year, of James Laurie, one of the best-known and most highly respected practitioners of Greenock. Though he had been in failing health for some time, he was engaged in practice a few weeks before his death. He was a native of Greenock, and after graduating M.B., C.M. at Glasgow University, he served as house-surgeon at Greenock Royal Infirmary, to which institution he was destined to give so much of his time and skill in later years. On leaving the Infirmary, he soon acquired a large general practice, but his chief interest was in surgery, and at an early age he was appointed visiting surgeon to the Royal Infirmary, a post he held for about thirty-five years.

Trained in the antiseptic school, he soon realized the importance of the new aseptic methods so strongly advocated by Macewen of Glasgow, and at an early period adopted these with great advantages to the institution. This was characteristic of the man, for he was ever on the lookout for new and improved methods. Laurie was unfailing in his attention to his hospital duties, and special mention must be made of the kindly interest he took in the nurses and house-surgeons who were trained under him. Many of the latter in all parts of the world look back with pleasure on their association with him. On his retirement he received a presentation from the staff, and his services were retained as consulting surgeon. For many years he rendered valuable service to the community as medical officer to Greenock Prison and to Smithston Asylum. He was also surgeon-accoucheur to the Greenock Maternity Hospital. During the war Laurie served as captain R.A.M.C. in the 3rd Scottish General Hospital. Mrs. Laurie was also active in war service, being honorary treasurer to the Scottish Women's Hospitals for home and foreign service, and during the war period the financial headquarters of that institution were established at the residence of Dr. and Mrs. Laurie.

Apart from his purely professional work, he did good service to his medical brethren as a member of the Burgh Insurance Committee from its establishment in 1913, and as a vice-president of the Medical Defence Union. He was a very active member of the British Medical Association, and served for several years before his death on the Scottish Committee. He was formerly president of the Glasgow and West of Scotland Branch. Dr. Laurie was one of the promoters of the first company of the Boys' Brigade in Greenock, and acted as surgeon. The meetings of the Greenock Faculty of Medicine were always enlivened by his cheerful presence and good humour. He was president for two periods, and ever ready to take part in discussions. Golf found in him an enthusiast. He was a member of the Glasgow Medical Golf Club, and was at one time captain of the Greenock Golf Club. He strongly advocated the formation of a municipal golf course in Greenock. An active Freemason, he was right worshipful master of Lodge Greenock Kilwinning for two years. To quote from a tribute in the local press: "His presence was so full of sunshine and merriment that at no time did the hand of death seem near to touching him. Even the passage of years took nothing from the clear ring of his laugh. He never seemed to grow older."

THE LATE DR. S. E. DENYER

Colonel C. J. WILLMER TATHAM writes: I should like to add my tribute to the memory of Dr. Stanley E. Denyer, whose death was noted in the *Journal* of March 14th. Throughout the war he served under me as sanitary officer to the Humber garrison, also as a member of all the medical boards on officers and men. He was an invaluable officer, not only for his professional knowledge, but for his delightful temperament. He was always *persona grata* with both officers and men of the regiments and training battalions in the command; all liked him and trusted him. In the arrangement and sanitation of the big camps in Holderness, and [illegible] Department and [illegible] disastrous period of the influenza epidemic, he was indefatigable. In his daily visits to the different areas he was a great help to the regimental medical officers as a diagnostician in doubtful cases. To myself, he was more than a valued colleague, he was a dear personal friend—always ready to help, never tired, never sick. I could ill spare him, though it was at the end of the war, when he was transferred at his own request to Alder Hey

Hospital. I knew him slightly in the South African war. I have always understood that he received the C.M.G. for taking command and bringing out of action the R.H.A. battery to which he was attached, when all the combatant officers of the battery were either killed or wounded. Examinations were never any trouble to him. With all his numerous degrees and qualifications, I can only recall one failure at an examination, and that he soon put right. Dr. Denyer's death at such an early age is a real loss, especially to the profession in Hull, where he had made for himself a high reputation. In the Service his name and his work will always be a precious memory to those who had the good fortune to know him.

Dr. W. H. LINE of Hockley Hill, Birmingham, died on March 10th. A colleague writes: Born at Daventry in 1855, William Henry Line was a student of Trinity College, Dublin, and obtained honours in both arts and medicine, graduating M.B., B.Ch. in 1880 and proceeding M.D. in 1881. He came to Birmingham forty-five years ago as superintendent of the Fever Hospital. Sir Gilbert Barling and the late Sir Bertram Windle also came to Birmingham about the same time, and the three were very great personal friends; always very keen on their work, they used to keep up their post-graduate studies by meeting in one another's rooms. Few medical men could be more beloved by their patients and medical colleagues than Dr. Line. He was a man of extraordinary memory and had great erudition, both in medicine and in general literature. His charming personality was a great delight to his friends, and especially to his medical colleagues. He did valuable work as teacher of vaccination at the Birmingham University, which position he held for over twenty years, resigning only two years ago. He was laid to rest at the Handsworth Cemetery. A service at St. Saviour's was very largely attended; the vicar, the Rev. Joseph, spoke most affectionately of "the old doctor," as he was known by his patients and friends.

We regret to record the death of Dr. GEORGE ROBERT LAWLESS. He took the diplomas of L.R.C.P. and S.I. in 1879, and that of F.R.C.S.I. in 1894. After serving as assistant medical officer to the District Asylum, Sligo, he was appointed in 1897 as resident medical officer to the Armagh District Asylum. During the war he held a temporary commission in the R.A.M.C., and did duty in Dublin. Dr. Lawless was for many years a member of the British Medical Association, and served as vice-president of the Section of Psychological Medicine when the Association held its Annual Meeting at Belfast in 1909. In 1914 he was president of the Ulster Branch, and since then had been a regular and enthusiastic member of the Branch Council, taking an active interest in the affairs of the Association. His charm of manner, unfailing courtesy, and cheery disposition endeared him to all who came into contact with him.

Dr. WILLIAM AYTON GOSTLING died on March 12th at his residence at Worthing, at the age of 76, from pneumonia following influenza. He was born at Diss in Norfolk and was educated at the City of London School, the Pharmaceutical College, and University College, London. He was a brilliant student at both institutions, taking several gold medals and the Atchison Scholarship and Filliter Exhibition for pathology at University College. He graduated with honours at the University of London, and won the gold medal at the M.D. examination in 1885. After holding the posts of house-surgeon, house-physician, and [illegible] assistant, at University College Hospital, he acted [illegible] as medical officer at Charterhouse School, [illegible] with Clarence Haigh-Brown, and then began [illegible] with Dr. Fuller of Regent's Park. He joined Dr. [illegible]sh at Worthing in 1887, and in 1890 they [illegible] Dr. Frank Hinds. He built up a large and complex [illegible] and did a considerable amount of consulting [illegible] neighbourhood until his retirement in 1920. [illegible] was a Fellow of University College, London, M.D. [illegible], and a few days before his death was honoured by an invitation to preside over its annual dinner. He served the British Medical Association as secretary and chairman of the Worthing Division. Dr. Gostling was a man of wide interests, and was an excellent photographer, a taste which his love of travelling gave him many opportunities of enjoying. He was genial and fond of entertaining his friends, by whom his death is felt as a great loss.

Universities and Colleges

UNIVERSITY OF OXFORD

The Radcliffe prize for the furtherance of medical science in the University has been awarded to W. H. Bradley, B.M., B.Ch. (Christ Church).

The electors have notified to the Master and Fellows of University College the election of K. N. Irvine, B.M. (Magdalen), to a Fellowship on the foundation of Dr. John Radcliffe.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examinations indicated.

DIPLOMA IN PUBLIC HEALTH.—*Part I.*: A. C. Briffa, S. Canter, R. F. Corlett, W. A. Davies, J. Hatton, E. W. Jones, J. N. Parrington, L. G. Thomas, A. J. Walsh, F. J. Welton, E. B. Whittingham.

DIPLOMA IN TROPICAL MEDICINE.—R. Behari, K. L. Bhambari, F. E. Camps, A. E. Carrol, P. E. J. Cutting, M. S. Eldin, E. R. Gauld, M. Kalra, E. W. H. Maass, H. A. Maniar, K. T. Moir (recommended for the Milne Medal), R. C. Speirs, Dorothy M. H. Tripp, J. Yunibandhu.

DIPLOMA IN TROPICAL HYGIENE.—L. J. A. Loewenthal, J. E. D. Mendis, F. O'Driscoll, J. K. Sung.

UNIVERSITY OF DUBLIN

TRINITY COLLEGE

The following degrees and licences were conferred on March 20th.

M.D.—R. A. Q. O'Meara (*stip. cond.*), G. W. F. Pratt, H. J. Robinson.

M.A.O.—S. H. Woods.

M.B., B.Ch., B.A.O.—C. H. Adderley, C. Bowesman, P. C. Cosgrove, H. W. Dalton, J. E. R. Keyms, S. Levy, Annie E. Thompson.

LICENCE IN MEDICINE, SURGERY, AND OBSTETRICS.—C. M. Elliott, J. M. McElligott.

The following have been approved at the examinations indicated:

FINAL M.B., PART I.—*Materia Medica* [illegible]; *Medical Jurisprudence and Hygiene*: [illegible] S. N. Varian, C. J. Hassett, M. [illegible].

PART II.—*Medicine*: P. C. Cosgrove, Elizabeth K. Roberts, T. F. O'Donnell, Margaret D. Gregg, C. H. Hutchinson, P. H. Peacock, Marjorie L. Campbell, W. A. Ryan. *Midwifery*: *D. Torrens, *G. A. Wray, *B. O'Brien, *J. Miller, D. B. Bradshaw, J. L. Martin, H. S. Mason, H. J. Eustace, A. J. Harden, M. A. Shapiro, I. G. M'Intyre, A. D. Barber, O. W. S. FitzGerald, W. A. Ryan, E. F. Burton, J. B. Fleming, Dorothy R. R. Solomons, P. W. O'Ryan.

* Passed on high marks.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

COUNCIL ELECTION

Monday, March 16th, was the last day for the receipt of nominations of candidates for the Council. The three retiring members—Mr. J. Herbert Fisher, Mr. G. E. Gask, C.M.G., D.S.O., and Mr. Graham Simpson—seek re-election, and the following candidates were also nominated: Mr. Herbert J. Paterson, C.B.E., Mr. H. S. Clogg, and Mr. A. James Walton.

The composition of the Council since July, 1930, has been as follows:

President.—Lord Moynihan, K.C.M.G., C.B., Council (1) 1912 (substitute), (2) 1919, President 1926.

Vice-Presidents.—Mr. C. H. Fagge, C. (1) 192[illegible] tive, Mr. R. P. Rowlands, C. (1) 1922, (2) 1930. [illegible] the (2) 1929; and

Other Members of the Council [illegible]s cough. (2) 1921, (3) 1929; [illegible] as they are, Robertson's papers well re[illegible] and I feel that Dr. Mitchell has done Roberts[illegible] service in drawing attention to his pioneer wor[illegible] an important branch of surgery.—I am, etc.,

East Suffolk Hospital, Ipswich, March 21st. WALTER RADC[illegible]

Sir V. Warren Low, C.B., C. (1) 1916 (substitute), (2) 1917, (3) 1926 substitute); Mr. Victor Bonney, C. (1) 1926 (substitute), (2) 1930; Sir G. Grey Turner, C. 1926; Mr. Hugh Lett, C. 1927 (substitute); Sir Leonard Gamgee, C. 1928 (substitute); Mr. R. G. Hogarth, C. 928; Mr. R. E. Kelly, C. 1928; Mr. Graham Simpson, C. 1929 substitute).

The medical schools are represented as follows:

London		Provinces	
St. Bartholomew's	4	Birmingham	1
Guy's	3	Bristol	1
London	1	Cardiff	1
St. Mary's	1	Leeds	1
Middlesex	2	Liverpool	1
St. Thomas's	3	Manchester	1
University College	1	Newcastle	1
		Nottingham	1
Total London	15	Sheffield	1
		Total Provinces	9

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have been approved in the subjects indicated:

SURGERY.—G. I. Benjamin, G. W. Hinchliff, D. R. Rigg, E. S. St. John, R. S. Wale.

MEDICINE.—W. A. Naidu, R. S. Wale.

FORENSIC MEDICINE.—F. Brodabl, G. C. Brown, H. R. Fosbery, R. S. Wale.

MIDWIFERY.—A. J. P. Coetzee, H. W. Davies, R. C. H. Ensor, R. P. Huggins, S. D. Jouhar, J. S. Lane, W. K. Schnarr, E. S. St. John, S. H. Thaler, R. S. Wale.

The diploma of the Society has been granted to Messrs. G. W. Hinchliff, W. A. Naidu, D. R. Rigg, W. K. Schnarr, and R. S. Wale.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The London Passenger Transport Bill, the report of Estimates for the Defence Services, and the Consolidated Fund Bill were discussed in the House of Commons this week. The Yarmouth Naval Hospitals Bill, which had not been reached on the previous week, was set down for second reading on March 27th.

Mr. Groves has given notice that on March 30th he will present a Bill to repeal the law relating to compulsory vaccination.

In the House of Lords the committee stage of the Pharmacy and Poisons Bill was put down for March 26th.

The Parliamentary Medical Committee met on March 24th and discussed the introduction of a Proprietary Medicines Bill. Dr. Alfred Cox attended for the British Medical Association. The committee decided that after Easter such a Bill should be introduced, to be backed by a medical and a lay member of Parliament of each party. The Bill is founded on the report of the committee which sat in 1914 and on the Bill of 1920. It will contain a schedule of diseases such as cancer and consumption, "cures" of which shall not be advertised, and will also provide for a register of proprietary drugs, medicines, and methods of treatment. The Bill will not go beyond the first reading stage this session.

The House of Commons will adjourn from April 2nd till April 14th.

Rules under Mental Treatment Act

In the House of Commons, on March 16th, Mr. GREENWOOD moved that the Mental Treatment Rules, 1930, made by the Board of Control, under Subsection (1) of Section 338 of the Lunacy Act, 1890, as extended by Subsection (1) of Section 15 of the Mental Treatment Act, 1930, should be approved. He said that the opportunity had been taken to consolidate the existing position so far as possible. The Act required that in any modification of the existing law the Department should consult the interests concerned. They had therefore consulted with the local authorities, the medical profession, the Mental Hospitals Association, and similar bodies. Since then, the Rules had been modified and published, and a measure of agreement had been reached.

Dr. MORRIS-JONES said that when the Mental Treatment Bill was before the House there was considerable perturbation generally as to whether the liberty of the subject was being properly safeguarded. He thought that these Rules were sufficient with regard to that particular matter. He had considerable sympathy with medical officers in all institutions who would have to work the Act. When he saw the complexity and variety of the schedules at the back of the Statutory Rules and Orders he began to wonder how a medical man in charge of cases would have time to look after the cases at all. He was not sure if this was not another tendency of the State to burden the medical profession with far more clerical work than it had the facilities to carry out.

Mr. GREENWOOD said that the schedules were elaborate, but medical officers were accustomed to dealing with these forms, and he did not think they would find them confusing.

Sir D. HERBERT asked for an explanation of Rule 22, which said that mechanical means of bodily restraint should not be applied to any temporary patient unless the restraint was necessary for the purposes of surgical or medical treatment. The question arose whether, if a person was a temporary patient, he put himself, under that Rule, in such a position that he could be forced by means of bodily restraint to undergo some surgical operation which, if he had the chance or choice to decide, he would prefer not to undergo. Mr. GREENWOOD pointed out that the wording of the Rule was a verbatim reproduction of Section 40 of the principal Act. Sir D. HERBERT said that that disposed of his point, in that the Rule was a reproduction of what was in the principal Act, and not a new enactment, except in so far as it applied now to a temporary patient.

The motion to approve the Rules was agreed to.

In the House of Lords, on March 24th, the LORD CHANCELLOR moved: "That the Mental Treatment Rules, 1930 (Statutory Rules and Orders, 1930, No. 1083), dated December 30th, 1930, and made by the Board of Control with the approval of the Lord Chancellor under Subsection (1) of Section 338 of the Lunacy Act, 1890, as extended by Subsection (1) of Section 15 of the Mental Treatment Act, 1930, which were presented on the 27th day of January, 1931, be approved so far as they modify or adopt any of the provisions of the Lunacy Act, 1890." He said the Rules had been submitted in draft to a number of interests concerned, including the medical profession. Many useful suggestions had been made in detail, which had nearly all been adopted. These Rules had been passed by the House of Commons. The Earl of ONSLOW said that the only real innovation in the Rules was the application of existing regulations to temporary and voluntary patients. The motion was accepted.

Indian Medical Department

Mr. BENN, replying on March 16th to Commander Kenworthy, said that, although the Indian Medical Department had a definite cadre, it was not an all-India service like the Indian Medical Service. Military assistant surgeons were attested as soldiers under the Army Act on first appointment. While they were in military employment their conditions of service were governed by Army Regulations, but on transfer to civil employment they came under the control of the civil authorities, which had full power to determine their rates of pay. In the circumstances he did not feel justified in suggesting to the civil authorities an increase in the rates, which they had decided were adequate. Commander KENWORTHY asked if it was not a fact that when the new pay and pensions of the Indian Medical Department were sanctioned they were for the whole unit, and that no difference was made between military and civilian members. Mr. BENN: No; the conditions of the Indian Medical Department and the Indian Medical Service are not quite comparable.

Commander KENWORTHY asked, on March 23rd, why, although the revised rates of pension were granted to all departmental officers of the Army in India in 1925, the Indian Medical Department was the only Department to which revised pensions were granted in 1927, two years later; and whether he would remove this distinction by granting the revised pensions from the date of sanction to all Indian Medical Department officers who retired from 1925. Mr. BENN replied

that pensions of departmental officers were reconstructed in 1925 on a basis of British rates which was inapplicable to the case of members of the Indian Medical Department. There was no necessary connexion between the two pension systems. When Indian Medical Department pensions were revised in 1927, the standing principle was applied that pension revisions could not be made retrospective. He did not feel justified in reversing that decision.

Post-vaccinal Encephalitis

Mr. GROVES asked, on March 19th, why the committee on vaccination was dissolved. Mr. GREENWOOD said that, with the presentation of its second report, this committee had sufficiently discharged its terms of reference after sitting four and a half years. Mr. GROVES asked why the final report did not refer to cases of post-vaccinal encephalitis during the period October 1st, 1929 to September 30th, 1930. Mr. GREENWOOD replied that such investigations occupied much time, and a date had to be fixed beyond which such cases would not be investigated for the second report. Only eight of these cases occurred within the dates named by Mr. Groves.

Insurance Practitioners

In a statement furnished to Mr. Thomas Lewis, on March 19th, Mr. GREENWOOD shows that at January 1st, 1931, 15,703 medical practitioners were undertaking national health insurance work in England and Wales. In the year 1930 the number was 15,750, and the amount paid to them £7,300,000. In 1929 the figures were 15,563 and £7,109,000; in 1913 the figures were 12,674 and £3,858,000.

Serum Treatment of Bovine Tuberculosis.—On March 16th Dr. ADDISON told Mr. Hurd that he had recently had under careful consideration the possibility of expediting research work into the value of the serum treatment of bovine tuberculosis.

Cerebro-spinal Fever.—Mr. SHAW, replying on March 17th to Mr. Groves, gave a tabulated answer showing the dates of admission to hospital, of the deaths where they occurred, and of the last vaccinations in the case of soldiers and their families admitted to hospital suffering from cerebro-spinal meningitis during this year up to March 12th. The statement showed that, of 31 patients admitted to hospital, 15 had died and 22 had been vaccinated since the beginning of 1929. No patients had yet been discharged from hospital.

Cerebro-spinal Fever and Vaccination.—In a statement circulated on March 23rd, Mr. SHAW said that, so far as was known, there was no relationship between cerebro-spinal meningitis and vaccination, nor any relationship between any form of cerebro-spinal disease, the causation of which had been associated with vaccination, and cerebro-spinal meningitis. There was no evidence that the present procedure in vaccination affected adversely the flow of recruits to the Army or the after-health of the men enlisted. There were therefore no grounds for altering the present rules on vaccination, which were designed to protect the troops from small-pox, a disease prevalent in many of the countries in which the Army was called upon to serve.

Disposal of London Refuse.—On March 12th, replying to Commander Kenworthy, Mr. GREENWOOD said that he had pressed the metropolitan authorities to discontinue insanitary dumping of refuse, and action had been taken, or was contemplated, by a number of them. Some authorities in the neighbourhood of London had made by-laws under which precautions could be enforced to prevent any nuisance from refuse tips. Returns for the year 1928-29 from 216 of the larger urban authorities showed that 138 (19 being in London) incinerated part or the whole of their refuse.

Medical Examination of School Children.—Mr. LEES SMITH stated on March 19th, that there was no universal dental examination of children entering school. Of children medically examined on entering school in 1929, 20.3 per cent. required some form of medical treatment. As a result of action by the Ministry of Health, the proportion was smaller than before the war.

Venereal Disease in the Navy.—Replying to Miss Wilkinson, on March 18th, Mr. ALEXANDER said that it had been the custom to remark upon the rise or fall in the incidence of venereal disease in the Navy only when the fluctuations were sufficiently large to warrant special investigation. This subject was receiving the constant attention of the Admiralty, and in future reports on the health of the Navy comment would be made with regard to any serious augmentation of the figures.

Colour Vision and the Navy.—On March 18th, during a debate on the report stage of the Navy Estimates, Lord ERSKINE said the medical examination imposed on cadets was very stiff. Very good men might be lost because of the stringent colour-vision test. To-day many people were colour-blind to a slight extent, but the system of selecting naval officers meant that they must have perfect sight. Many German naval officers during the war wore spectacles, but that did not diminish their efficiency at sea. Mr. ALEXANDER said that Lord Erskine himself would not care to sleep in a ship with a colour-blind officer on the bridge. The tests which were carried out were on a new technical basis for discovering colour-blindness, and were so perfect that cadets experienced no injustice on that ground. He wished to leave the whole subject for consideration on receipt of a report from a committee set up last year.

Aniline Workers and Cancer.—Replying to Mr. Philip Oliver, on March 18th, Mr. SHORT said the investigation being carried out by the London Cancer Hospital, with the assistance of the medical inspectorate of the Factory Department, into the incidence of the disease of cancer of the bladder among workers in aniline factories had been actively continued, but so far there were no conclusive results to report. The question of approaching the life assurance offices had been considered, but they would not be able to furnish information of material value which was not obtainable from the Registrar-General.

Notes in Brief

Mr. Clynes promises that when opportunity comes to revise the Workmen's Compensation Act consideration will be given to the suggestion that nurses and other persons employed at isolation hospitals should be included.

In England and Wales during 1930, 38,790 deaths were registered of infants under 1 year of age.

Mr. Montague told Mr. Groves, on March 18th, that there had been twelve cases this year of cerebro-spinal meningitis among the Royal Air Force personnel; of these six proved fatal.

The Services

NAVAL MEDICAL COMPASSIONATE FUND

A meeting of the subscribers to the Naval Medical Compassionate Fund will be held on April 16th, at 3 p.m., at the Medical Department of the Navy, Queen Anne's Chambers, Tothill Street, Westminster, S.W.1, to elect six directors of the Fund.

DEATHS IN THE SERVICES

Lieut.-Colonel Arthur Farrington Carlyon, R.A.M.C. (ret.), died on March 13th in the Middlesex Hospital, after an operation, aged 57. He was born on April 15th, 1873, and was educated at the Middlesex Hospital. After taking the L.S.A. in 1899, he entered the R.A.M.C. as lieutenant on December 4th, 1899, became major after twelve years' service, and lieutenant-colonel on December 20th, 1917, and retired on September 9th, 1922. He served in the South African war in 1899-1902, taking part in operations in the Orange River Colony and in Cape Colony, and received the King's and Queen's medals, with two clasps to each.

Lieut.-Colonel William Henry Thornhill, Madras Medical Service (ret.), died in London on March 17th, aged 76. He was born on December 3rd, 1854, the son of John Thornhill of Shandon, Cork, and was educated at Queen's College, Cork, graduating as B.A. in 1873 and as M.D. and M.Ch. in 1877, of the Queen's University of Ireland. He also took the L.K.Q.C.P. in 1876, and the L.R.C.S.Ed. in 1877. Entering the I.M.S. as surgeon on October 1st, 1877, he became surgeon lieutenant-colonel after twenty years' service, and retired on April 9th, 1899. He served in the Afghan war of 1879-80, receiving the medal, and in Burma in 1887-88, medal with clasp. After his retirement, he was in practice in Pimlico for nearly thirty years. He was a regular attendant at the annual I.M.S. dinner, where for some years past he had usually been the senior officer present.

Medical News

A number of special courses have been arranged by the Fellowship of Medicine to take place after the Easter holidays. From April 13th to 18th the Prince of Wales's Hospital, in association with the North Middlesex Hospital, will hold a course in gastro-enterology. Instruction will be given from 10.30 a.m. to 5.30 p.m., and both the medical aspect and the surgical aspect will be dealt with; fee £4 4s. A course in venereal diseases will be given at the London Lock Hospital from April 13th to May 9th; fee £2 2s. An all-day course in diseases of the chest will take place at the Brompton Hospital from April 20th to 25th; fee £3 3s. From April 27th to May 9th there will be a morning course at the Hospital for Sick Children; fee £5 5s.; and, covering the same period, an afternoon course at the Infants Hospital; fee £3 3s. From April 21st to May 30th a comprehensive afternoon course in psychological medicine will be undertaken by the staff of the Maudsley Hospital; fee £5 5s. From April 27th to May 23rd an intensive course at the Central London Throat, Nose and Ear Hospital has been arranged, and is divided into the following classes: clinical, fee £5 5s.; operative, £7 7s.; peroral, £6 6s.; and pathology, £5 5s. The classes are all limited with the exception of the clinical, so that early enrolment is desirable. Copies of all syllabuses as well as particulars of the general course will be sent on application to the Fellowship of Medicine, 1, Wimpole Street, W.1.

The house and library of the Royal Society of Medicine will be closed from Thursday, April 2nd, to Tuesday, April 7th, both days inclusive.

The annual general meeting of the governors of St. Mark's Hospital, City Road, E.C., was held on March 19th. In the absence of the Lord Mayor, the chair was taken by Alderman and Sheriff Maurice Jenks, who said that the hospital now had a completely equipped research laboratory where some promising investigations into the cause of cancer were being carried out in alliance with the British Empire Campaign. Mr. J. P. Lockhart-Mummery, honorary surgeon to the hospital, in acknowledging a vote of thanks to the committee of management and the medical officers, pointed out that during the past three or four years it had been possible to provide a certain number of private wards, which had been greatly appreciated by the public, ninety-three patients having been admitted in 1930. As at times the demand for admission had far exceeded accommodation, it was hoped in the future to increase the number of those wards. A small lecture theatre was being built in connexion with the research laboratory in order that there might be an increase in post-graduate lectures and demonstrations dealing with various aspects of diseases of the rectum. Mr. Swinford Edwards, honorary consulting surgeon, referring to the recent alterations which had taken place, said that the new building was practically double the size of the old.

The Irish Medical Schools' and Graduates' Association held its St. Patrick's Day dinner at the Piccadilly Hotel, London, on March 17th, under the chairmanship of Mr. Andrew Fullerton, professor of surgery, Queen's University, Belfast. After the usual loyal and patriotic toasts, Dr. W. Mulhall Corbet proposed the "Health of the Guests," mentioning that the association was honoured by the presence of Lord Russell of Killowen. In the course of his reply Lord Russell gave an outline of the history of St. Patrick, noting his miracles and the outstanding traits of his character. He commended the association for its motto: "Floreat Hibernia Semper." In the absence of Sir F. O'Connor, the toast of "The President and Association" was proposed by Dr. Hall Morton, governor of Holloway Prison, who said that he met very few Irishmen, but in his job that was natural. The association was a splendid organization for the promotion of unity and friendship among the medical graduates of Ireland resident in London. In reply, Mr. Andrew Fullerton said that the Irish nation had provided many of the best brains of the Empire. Its great traditions of genius, perseverance, and industry were universally recognized. During the evening a musical programme was provided by Miss Nellie Walker and Mr. Frederick Gregory, with Miss Kathleen O'Hagan as accompanist. Lord Russell and Wing Commander William Tyrrell showed their versatility by singing Irish songs, which were received with enthusiasm.

A report appeared in the *Journal* of December 20th, 1930 (p. 1058), of the conference organized by the Central Association for Mental Welfare, and held in the Great Hall of B.M.A. House on December 11th, 12th, and 13th. The full text of all the papers and discussions has now been published, and copies (3s. 6d.) may be obtained from the honorary secretary, Miss Evelyn Fox, 24, Buckingham Palace Road, S.W.1.

Arrangements have been made for a party of English medical men to visit the Rhineland spas at Easter. The members will leave Victoria Station at 10 a.m. on Wednesday, April 1st, and travel to Germany via Ostend. The places to be visited include Aachen (Aix-la-Chapelle), Neuenahr, Coblenz, Nauheim, Homburg, Wiesbaden, and Cologne. The party will return to London from Aachen on April 10th. The tour is being organized by Mr. R. O. Rohme, 90, Sheaveshill Avenue, Colindale, N.W.9.

The seventh French Congress of Tuberculosis will be held at Bordeaux from March 30th to April 2nd, and will be followed by visits to the principal institutions organized by the Campaign against Tuberculosis in the south-west of France.

The sixth section of the first Italian Congress of Colonial Studies, to be held at Florence from April 8th to 12th, will be devoted to tropical pathology and hygiene under the presidency of Professor Gabbi. Further information can be obtained from Professor Persano, Via Laura 48, Florence.

The third Congress of the Italian Society of Microbiology will be held at Milan from April 19th to 21st.

The following German congresses will be held in April: Balneological Society at Ems, 7th to 12th; Surgical Society in Berlin, 8th to 11th; Psychiatric Society at Breslau, 9th and 10th; Society for Internal Medicine at Wiesbaden, 13th to 16th.

The next congress of the International League against Rheumatism will be held in Rome from May 19th to 24th, when the following subjects will be discussed: the early symptoms of chronic rheumatism; rheumatic diseases and tuberculosis; and rheumatic diseases and occupation.

The Soviet Commissariat of Health has issued an interesting illustrated report on tuberculosis in the Ukraine, containing articles in English, French, and German on the incidence of the disease by Dr. N. Morosowski, the methods of prophylaxis by Dr. L. Trachtmann, and the tuberculosis institutions in the Ukraine by Professor I. Feinschmidt. An extensive bibliography of recent Russian literature is appended to each article.

An international fund is to be raised for the erection of a monument in Rome to Carlo Forlanini, who introduced the artificial pneumothorax treatment for pulmonary tuberculosis.

At a recent meeting of the Federation of the Latin Medical Press, Dr. Léopold Mayer of Brussels was elected president, in succession to Professor Maurice Loeper of Paris, with Drs. Ascoli of Italy, Dominguez of Cuba, and Forgue of France as presidents of honour.

Dr. Achard, professor of clinical medicine in the Paris Faculty, and Dr. Le Mée, an eminent oto-rhino-laryngologist, have been made commanders of the Legion of Honour.

Dr. Rollier of Leysin and Dr. Chagas of Brazil have been elected foreign members of the Académie de Médecine.

Dr. Lenormand, professor of surgical pathology at the Paris Faculty of Medicine, has been elected president of the French Society of Surgery.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, *on receipt of proofs.*

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

A Case of Dyspnoea

Dr. E. P. POULTON (London, W.) writes in reply to "G. D. G.'s" query concerning a case of dyspnoea (March 7th, p. 431): I would suggest his administering oxygen at the beginning of the attack from a 40-foot cylinder by means of a rubber bag, with mask and valves, such as is used for giving nitrous oxide. Injections of adrenaline 1 in 1,000 in the early part of the attack should also prove of value.

Sensitiveness to Sunshine

Dr. ARTHUR WHITFIELD (London, W.1) writes: In answer to the query of "A. S. P." (Liverpool) in last week's issue (p. 523), I believe he will find the following useful. The parts to be exposed are swabbed over in the morning after washing with—

Acid tannic	ʒ vjss
Sp. vini meth. indust.	ʒ ij
Aq. dest. ... ... ad	ʒ viij

and allowed to dry. Although invisible, this lotion filters the rays and gives the skin protection. It is a preventive, not a cure, and was devised by Professor Kreibich of Prague. Severe sweating washes it off slowly, and sea-bathing, of course, quickly, so that after either it should be renewed at once. I have yet to learn of a failure. At the same time, investigation for metabolic errors should be undertaken, especially if the sensitiveness is a recent acquisition.

Paroxysmal Rhinorrhoea

Dr. A. DANGERFIELD (Corfe Castle) writes in reply to the query by "Ninety-nine" (March 7th, p. 432): I hope the following will be found of use: 1/4 tablet of racedrin (Bayer) night and morning, taken orally. Also, anaesthesin (20 grains), liq. adrenaline chlor. (20 minims), vaselin. alb. (2 drachms), and paraff. liq. (2 drachms), applied to the nose thrice daily. I usually tell the patient to push with the tip of the little finger a piece about the size of a pea as far as possible up each nostril, and then to lie flat on the back, with the head well back, for two or three minutes, sniffing gently and repeatedly during the period, so that the vaseline melts and runs right through the nose. It seems to me that the case is allergic, and, if so, this treatment may give great relief. I shall be interested to hear the result.

Income Tax

First Year of Practice

"T. M. M." took over his practice as from January 1st, 1930. The inspector proposes to assess him for the year to April 5th, 1931, on the basis of the earnings for the year to December 31st, 1930, but claims to bring in the amount [illegible] of its outstanding at that date as part of the profits. He [illegible] says that "an adjustment is due" as regards debts existing from the old practice. Is this correct?

*** In the first place, the inspector is correct in refusing to adopt the "cash basis" for computing the profits of the first year. The tax is chargeable on the full amount of the profits, whether they have been received or not, and, in fact, expenses for a whole year will be charged, and must therefore be set against a full year's receipts. But the gross amount outstanding at the end of the year should not be added to the cash receipts without some allowance for probable loss by bad debts, etc. "T. M. M." should examine the list of unpaid accounts as at December 31st, 1930, and note against the various items what he considers each probable loss will be, and claim the aggregate of those amounts as "bad and doubtful debts." In the second year there will have to be added to (or deducted from) the cash profits the increase (or decrease) in the net value of outstanding debts at December 31st, 1931, as compared with December 31st, 1930—and so on in future years. With regard to the debts due to the old practice we cannot see what adjustment is due. If tax has been paid on the cash profits for recent years, then it has been paid on account of the full profits, inasmuch as in the case of a long-established proprietorship the amount of the gross receipts and of the value of the gross bookings are normally the same.

LETTERS, NOTES, ETC.

Graves's Disease: Intercurrent Pyrexia

Professor GEORGE R. MURRAY (Manchester) writes: The case of Graves's disease described by Dr. J. G. Bennett in the *Journal* of March 14th (p. 480) is remarkable in that decided improvement, lasting for several weeks, occurred after each of four or five attacks of influenza. As far as my experience goes this is a very unusual result. I have seen so many cases of Graves's disease in which the symptoms have been aggravated by an attack of influenza that I advise patients suffering from any form of hyperthyroidism to take every possible precaution to avoid the infection of influenza, as this exacerbation may last for several weeks or months. It would be interesting to know the experience of others who are observing the effect of influenza and kindred infections on the course of this malady.

Nord-Sud Tours in Italy

Dr. J. HENRY STORMONT (Worthing) writes: By the merest chance I heard last spring of an international medical tour, organized by the Italian Government through the Italian State Railways and the E.N.I.T., and a brief note may be of interest to your readers. Similar tours are now organized in France and Spain, but the Italian tour is noteworthy in three particulars: the unique beauty of the country toured, the very small "busman's holiday" factor, and the remarkable comfort and efficiency with which it is organized by Professor Guido Ruata of Rome. The tour is not advertised, for it is limited to 150 members, of which the English-speaking group can comprise forty or fifty, but it deserves to be more widely known in the profession. The eighth tour begins at Rome on September 19th next, and includes the Naples Riviera, Capri, Sorrento, Amalfi, etc., and after visiting Taormina ends at Palermo on October 2nd. The cost of the tour is a smaller item, as a rule, than the travel fares there and back. Professor Ruata tells me, in reply to a letter, that he will be in London for the last week of March, and will give full details to anyone interested, through Messrs. Thos. Cook and Sons' head office, Berkeley Street, W.

Chilblains

"A. M." writes: I have often advised patients for various conditions to take hot foot-baths, and sometimes order hot sea-water for the purpose. Dry sea-salt can be obtained in packets. I have been struck by the regularity with which they report later, "I've never had a chilblain since I did it." A predisposing cause of pernio is the common habit of keeping the boots on all day; the feet and footwear become thoroughly damp with perspiration, and chilled. Every effort should be made to remove the boots at least for a brief interval, and, if possible, to change into dry socks or stockings.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 50, 51, 54, and 55 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52 and 53.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *103*.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

295 Asthma Intensified by Liver Therapy

E. MATZGER (*Journ. Amer. Med. Assoc.*, January 10th, 1931, p. 110) reports a case in which the administration of liver extract intensified attacks of bronchial asthma, and suggests that this form of treatment may give rise also to other allergic manifestations such as gastro-intestinal disturbances and skin eruptions. The author's patient, aged 36, had suffered for several years from bronchial asthma dating back to bronchitis in childhood. He was treated with horse serum without reaction. A diagnosis of primary anaemia was made subsequently, the blood count being red cells 1,850,000, and leucocytes 1,900 per c.mm.; the colour index was 1.3. The patient then commenced a diet of raw liver, to which the anaemia responded after two weeks. The bronchial asthma, however, became continuous at the end of the first week of treatment and persisted until the liver was discontinued; a satisfactory blood picture was, nevertheless, maintained without further treatment. A year later the bronchial asthma recurred, but yielded to some extent to immunization by pollen and house dust. Raw liver was given a second trial, but was immediately followed by exacerbation of the asthmatic symptoms, which ceased as soon as the treatment was stopped. Desiccated hog stomach maintained a healthy blood picture without causing asthma. Cure of the asthma was eventually obtained by full immunization to pollen and house dust.

296 Etiology of Addison's Disease

As the result of fifteen years of physiological and clinical study of suprarenal insufficiency J. M. ROGOFF (*Canadian Med. Assoc. Journ.*, January, 1931, p. 43) has come to the conclusion that Addison's disease is not so much a manifestation of absence or failure of function of the medullary adrenaline secretion as the absence or lack of function of the cortical part of the gland. Experimental evidence obtained from dogs indicated that the loss of both glands caused symptoms which were entirely due to the loss of the cortex; certain cortical extracts were eventually obtained which were effective in prolonging life in such dogs, despite the excision of their suprarenals. Rogoff ascribes great importance in clinical diagnosis to the aversion displayed as regards fatty foods by patients suffering from Addison's disease, and also to a dull ache or pain in the back in the costo-lumbar angle on the side where at the subsequent necropsy extensive suppuration or caseous degeneration is demonstrable. He found that whereas the administration of adrenaline in such patients proved ineffective, an extract of the cortical portion of the gland was markedly beneficial, particularly when associated with intravenous injections of physiological saline solution, or Ringer's solution, to which is usually added 2 to 6 per cent. of dextrose. Addison's disease is, he adds, much more rapidly fatal in blonde patients than in brunettes.

297 Atypical Haemophilia

J. FLESCH (*Med. Klinik*, January 23rd, 1931, p. 127) discusses atypical forms of haemophilia, and reports the case of a boy, aged 5 years, who had severe colic relieved after the passage of stools mixed with blood, and suggesting appendicitis or volvulus. Three days later a tense sausage-shaped mass, associated with the typical blood count, indicated the probability of intussusception. Flesch, having discovered a familial history, diagnosed subserous haematoma, producing pressure symptoms. The melaena ceased, the swelling disappeared, and the boy recovered. At the age of 7 this boy had severe dyspnoea, with retrosternal pain and other signs of mediastino-pericarditis, without fever; the pain subsided in a few days, and he recovered, evidently from mediastinal haemorrhage. Two years later circumcision was performed, and haemorrhage from the stitches was arrested by injection of horse serum. After four years of good health an attack of vomiting caused severe dyspnoea with stridor, and a laryngeal examination revealed extensive submucous haemorrhage with oedema of the glottis. Subsequently painless haematuria with progressive anaemia ensued. Haemorrhage was unilateral and intermittent, coming from the renal pelvis or calyces, as was shown by attacks of renal colic. As regards diagnosis, the author states that non-traumatic haemophilic haemorrhage ceases spontaneously sooner or later; examination of the urine and the urobilinogen content confirms the diagnosis. He believes that most haemophilic arthralgias are of haemorrhagic origin; they progress towards arthritis and ultimate ankylosis, giving characteristic *x*-ray appearances. After the crisis the blood-coagulation time is prolonged or normal. The blood platelet count is almost always normal. Treatment is disappointing.

298 Intestinal Perforation in Paratyphoid B Fever

R. DAMADE and F. PAPIN (*Gaz. Hebd. Sci. Méd. de Bordeaux*, January 18th, 1931, p. 35), who records an illustrative case, state that while intestinal perforation in typhoid fever is well known, only a few examples of this complication have been recorded in paratyphoid fever. The first two cases were published by Chevrier and Grenier respectively in 1913, and subsequently cases were reported by Rathery in 1916, Cornil in 1924, and Pop in 1929. In his Bordeaux thesis of 1930 Latouche collected 14 cases of perforative peritonitis and 3 cases of non-perforative peritonitis in the course of paratyphoid A, B, and C. The prognosis of perforation in paratyphoid seems to be less unfavourable than in typhoid fever, since of 9 operation cases recorded by Cornil, 5 patients recovered, and of Latouche's patients who had been operated on, 3 recovered, while the 6 who were not so treated died. The present authors' case was that of a girl, aged 17, who developed intestinal perforation in the second week of paratyphoid B fever; until then it had been regarded as influenza. An operation was performed, and her subsequent recovery was uneventful.

Surgery

299 Recklinghausen's Disease of Bone

M. P. MULLER (*Bull. et Mém. Soc. Chir. de Paris*, December 19th, 1930, p. 785) reports the case of a woman, aged 40, who had fallen and was admitted to hospital with a fracture of the right femur. Traction was continued for two months, but at the end of this time there were no signs of bony union. A radiogram showed decalcification of the bone, with the presence of a bone cyst at the site of fracture. A bone graft, consisting of a portion of rib fixing the bone ends together, was inserted, but after a further two months bony union had still not taken place. Histological examination of the fragments removed at the time of operation showed disappearance of the osseous lamellae and a medullary fibroplastic metaplasia with multinucleated giant cells. In view of the chronic character of the bony lesions, a diagnosis of Recklinghausen's disease was made. A few months later the left femur and right arm were also fractured, and *x*-ray examinations in each case showed decalcification of these bones and also of the rest of the skeleton. There had been a total of seven fractures during a period of two years. In most cases this disease begins in infancy, but is not necessarily associated with rickets. In the case reported the Wassermann reaction was positive, but antispecific treatment had no effect on the disease, and syphilis did not appear to be the causative factor.

300 Joint Disease from Frost-bite

A. v. TEMPSKY (*Zentralbl. f. Chir.*, February 7th, 1931, p. 339), who records an illustrative case, states that while joint disease, and especially osteochondritis due to mechanical trauma, is well known, very little has been written about the relation of thermal factors to the development of joint affections. His patient was a lad, aged 20, who contracted extensive frost-bites on both hands while ski-ing. Bullae developed on the extensor aspects of the fingers and backs of the hands, which became very cyanotic and swollen. Gangrene occurred in the ring and little fingers of the right hand and little left finger, necessitating amputation of the last two phalanges of each finger. An *x*-ray examination showed severe destructive lesions of the joint between the proximal and second phalanges of the right little finger, while in the joint between the second and terminal phalanges of the right index and middle fingers the normal structure of the joint was completely destroyed, and less clearly marked lesions were found in the interphalangeal joints of the left ring finger. It is noteworthy that the affected joints appeared quite normal in the skiagrams taken immediately after the hands had become frozen, and the changes were first detected a year later. A similar case with late development of joint lesions has been reported by Löhr.

301 Duodenal Fistula

J. MURARD (*Bull. et Mém. Soc. Nat. de Chir.*, December 27th, 1930, p. 1458) divides duodenal fistulae into two groups—namely, spontaneous fistulae following a natural opening occurring at the site of a periduodenitis, and those which occur after operation for a perforated ulcer. The latter may be due either to failure in suturing or to the presence of a drainage tube. Different forms of drainage are discussed; a gauze drain is advocated as being less likely to cause a fistula. Murard records the case of a man, aged 68, in which gauze drainage was used; although the patient died from softening of the brain, there was sufficient time to see that, following the removal of the gauze drain on the fourth day, the wound had healed without fistula. In another case it was impossible to close the perforation, which was plugged; although a duodenal fistula developed, it healed spontaneously at the end of three weeks. Indications for using a gauze drain are the impossibility of closing the perforation or of evacuating the peritoneal exudate, and infection at the seat of the perforation. An established fistula may be treated indirectly by a gastro-enterostomy, which may be completed or not by a cholecysto-gastrostomy, or directly by suturing the edges of the opening, or by means of a partial duodenectomy with the re-establishment of the continuity of the duodenum. Indirect treatment is advocated in cases of posterior fistula, and the direct method for anterior fistula. In the majority of cases duodenal fistulae will close spontaneously in about three weeks, but in certain cases this does not happen, possibly owing to the passage of bile through the fistula, which hinders healing.

302 The Surgical Treatment of Angina Pectoris

D. DANIELOPOLU (*Presse Méd.*, December 27th, 1930, p. 1789) discusses the various operations that have been devised for the relief of angina pectoris. He refers to the operations involving extirpation of the stellate ganglion, and shows that they are apt to be followed by severe congestive heart failure. This he believes to be due to interruption of those sympathetic fibres which augment the force and rate of the heart, while increasing the blood pressure and dilating the coronary arteries. The author quotes animal experiments supporting this view, and remarks that such groups of patients in whom this operation has been performed without serious mortality have not been cardiac patients. The introduction of surgical treatment into current cardiological practice is thought to be desirable, but only if it were indispensable would extirpation of the stellate ganglion be justifiable, and only then in a patient in danger of death from frequent severe anginal attacks. The author claims that angina may be relieved by operation without excision of the stellate ganglion; he advises cervical sympathectomy combined with division of those branches of the vagus supplying the thorax and the rami communicantes uniting the inferior cervical and first thoracic ganglion to the three last cervical pairs; section of the first dorsal and the vertebral nerves is also performed. Among 28 patients operated upon in this way by various workers no fatality has occurred. Moreover, in the great majority there has been complete or almost complete relief from attacks for periods varying from one to five years. Sometimes operations on both right and left sides are necessary. In view of these results, operations involving extirpation of the stellate ganglion are considered not only dangerous, but also unnecessary.

Therapeutics

303 Treatment of Carbohydrate Dyspepsia

A. F. HURST and F. A. KNOTT (*Quart. Journ. of Med.*, January, 1931, p. 171) define intestinal carbohydrate dyspepsia as due to the defective fermentation of starch with consequent gas production and the formation of acetic, butyric, and other organic acids in the caecum and ascending colon. In the treatment of severe cases of this condition the authors recommend the exclusion of rice and of vegetables of every kind, but in milder cases green vegetables can be permitted in soups, and only root vegetables, cauliflower, and rice need be forbidden. In most cases as recovery proceeds the restrictions can be gradually lessened until, finally, potatoes alone are prohibited, a restriction which is often necessary for the remainder of the patient's life. With each meal an active preparation of an amylolytic ferment is administered, and it is found that with this aid the diet need not be so severely limited. Vegetable diastase is more resistant to the gastric acid than the amylopsin of pancreatic extracts, and is therefore preferable. Powdered charcoal was found to be quite unnecessary if a sufficiently strict diet was ordered. In severe cases with much diarrhoea the administration of a teaspoonful of chalk three times a day hastened recovery, the irritating organic acids being neutralized thus as fast as they developed. The authors consider vaccine treatment and colonic lavage useless. In view of the occurrence of this condition in many neurasthenic and psychasthenic patients, the importance of diagnosing it and treating it suitably by dieting is particularly notable by reason of the insomnia with which it is often associated, and which fails to respond to such drugs as medinal and luminal.

304 Digitalis in Pneumonia

J. WYCKOFF, E. F. DUBOIS, and I. O. WOODRUFF (*Journ. Amer. Med. Assoc.*, October 25th, 1930, p. 1243) report a series of pneumonia cases; simultaneous observations under identical conditions were made on similarly selected groups of patients treated with digitalis, and patients from whom digitalis was withheld. Class A were given neither serum nor digitalis; Class B had serum only; Class C digitalis only; and to Class D patients was administered both serum and digitalis. Patients were received into the "pneumonia series" according to the date and hour of admission, and alternate patients were treated with serum. This system of classification operated in each ward independently of other wards, so that factors of general care and nursing might be the same for each class of treatment. No evidence was obtained that routine digitalis therapy in lobar pneumonia resulted in a lowered mortality. About 95 per cent. of the patients had sinus rhythm throughout, but the only consistent signs of digitalis action were electrocardiographic changes and mild toxic effects. Digitalis toxicity was not a sufficient guide to prevent increase in mortality when the drug was used. The amount of the drug employed was found a better guide. When the digitalis was given in dosage too small to show any effect it caused no changes in mortality. When the doses were

comparable with the amount usually needed in the treatment of heart failure it affected the P-R interval and T-wave of the electrocardiogram, but caused little change in mortality. Auricular fibrillation and auricular flutter occurred rarely—in less than 5 per cent. of all cases. The authors think that digitalis might perhaps have been life-saving in an occasional patient in whom there was fibrillation or flutter, but, on the other hand, such patients frequently recovered without digitalis. They conclude that the routine giving of digitalis to patients with lobar pneumonia is dangerous.

305 Iodine Therapy in Exophthalmic Goitre

A. S. JACKSON and G. H. EWELL (*Amer. Journ. of Surg.*, December, 1930, p. 475) call attention to the danger of the prolonged administration of Lugol's solution in exophthalmic goitre. After a period of improvement when the patient gains weight, the heart and tremors quiet down, and the eye and mental symptoms diminish, there follows a stage in which a condition of "iodine fastness" develops, there being a tolerance to the drug characterized by elevation again of the metabolic rate, and the appearance of signs of myocardial damage with auricular fibrillation. An operation in such circumstances is fraught with grave risk, and the conclusion is drawn that the operation should not be delayed, but be performed in one or two stages as soon as the iodine medication has rendered it possible. The authors discuss the conflicting theories held as to the way in which the administration of iodine affects the enlarged thyroid gland; they believe that mechanical compression of the cells, with temporary inhibition of the action of nearly all areas, is an explanation which is supported by the pathological evidence. They emphasize the point that iodine therapy must not be considered as a curative procedure in goitre, where it has only a temporary palliative effect.

306 According to various authors, the clinical remission in cases of hyperthyroidism treated by iodine is accompanied by involutionary changes in the gland, and GEBELE (*Münch. med. Woch.*, February 6th, 1931, p. 225) reports a special study of the condition of the vessels in a number of thyroid glands removed at operation. Macroscopically, the glands from cases prepared by iodine therapy were found to be paler and firmer than the others; histologically, the non-treated glands show pronounced dilatation of the vessels—especially of the venules and capillaries of the interlobular septa—which is much less evident in the iodine cases. This lack of vascular engorgement appeared to bear a relation to the amount of iodine given. Gebele believes that iodine causes a rapid accumulation of colloid in the acini of the gland; this exerts pressure on the thin-walled veins and capillaries, thus probably hindering the absorption of thyroxine. If the administration of iodine is long continued the distension passes off, and toxic absorption recommences. Hence, as is well known, the iodine effect is usually a temporary one.

Radiology

307 Radiology in Urinary Diseases

J. MOMBAERTS (*Le Scalpel*, January 24th, 1931, p. 114) discusses the advantages and disadvantages of uroselectan in the diagnosis of renal disease. The drug contains 40 per cent. of organically fixed iodine; after its intravenous injection 96 per cent. is excreted in the urine in eight hours. It is non-toxic, and opaque to *x* rays even in high dilution. A considerable objection to its use is the variable time of excretion, necessitating the employment of a large number of *x*-ray plates. The procedure is indicated: (1) when ureteral catheterization is impossible, or as an alternative to it after cystotomy, or in place of exploratory lumbotomy; (2) as a last resource in doubtful cases; (3) when low pyelography is dangerous, as in cases of known bilateral kidney disease, or horseshoe kidney; and (4) in asymptomatic cases of doubtful etiology, when the use of uroselectan may draw attention to the renal tract.

308 The Results of X-Ray Treatment in Graves's Disease

P. HESS and H. SCHLECHT (*Münch. med. Woch.*, January 9th, 1931, p. 55) report a series of 29 cases of exophthalmic goitre and hyperthyroidism which were treated by *x* rays: 93 per cent. were cured or definitely improved. The cases varied in severity, but in nearly all the basal metabolism was raised 20 per cent. or more. The method generally adopted by these workers was to submit the patient to three series of exposures at an interval of four to six weeks; each series consisted of three exposures on successive days, and at each the right and left sides of the neck and the thymus were irradiated. The course of the treatment was, however, in every case controlled by the reduction produced in the basal metabolism, and in no case was the patient exposed to further *x* rays when this approached normal. The ultimate response to the treatment was often delayed for a long time, the average in this series being sixteen months. The authors point out that this slow response has been disregarded in former comparisons of the results of *x*-ray and surgical treatment in hyperthyroidism and exophthalmic goitre. If the patient can spare sufficient time, they consider that the results of *x*-ray therapy compare very favourably with those of surgery, while the mortality of the former is *nil*.

309 Treatment of Pituitary Tumours

Of 23 cases of pituitary tumours dealt with at the Brünner Ophthalmic Clinic, V. MAZAL (*Bratislavské Lekárske Listy*, December, 1930, p. 197) states that 18 were subjected to *x*-ray treatment, 2 were treated surgically, and 3 had no treatment at all. Of the eighteen treated radiologically twelve improved, two remained unchanged, two became worse after an initial improvement, and two others became worse immediately following the treatment. Of the two operation cases, one improved. The author concludes that treatment must be individual. Undoubtedly most cases improve under *x* rays properly applied, but certain cystic growths and very rapidly growing tumours giving rise to acute increase of intracranial pressure and rapid deterioration of vision should be handed over to the surgeon.

Obstetrics and Gynaecology

310 Syphilis of the Cervix

In a review of syphilis of the cervix J. J. PUENTE (*Bruxelles-Médical*, February 6th, 1931, p. 408) reports 29 cases of primary cervical chancre, and 28 others which were diagnosed as secondary syphilitic lesions. All the cases were examined and treated at the Rivadavia Hospital (Buenos Ayres) between 1921 and 1930. Among genital chancres observed during this period, 16 per cent. were chancres of cervix, a notable increase as compared with the previous decade. The situation of the chancre in 18 out of 28 cases was in the neighbourhood of the external os. In the remainder it appeared on one or both lips of the os itself. Clinically, the appearance was usually papular, but sometimes ulcerated or hypertrophied. The diagnosis of syphilitic chancre of the cervix rested on the presence of a raised ham-coloured papule, or an ulcer with an infiltrated base situated on or near the os. The exudate was yellow, with minute haemorrhagic points. The surface was finely granular, but after friction would become smooth and shining from the presence of an abundant serous secretion. At the periphery of the papule tiny telangiectases were seen. The most important and constant characteristic was the firm, hard consistence. The specific spirochaetes were found relatively easily in the eccentric lesions, provided that they were carefully cleansed, but sometimes several investigations were necessary to distinguish *S. pallida* from other spirochaetes. Pathological sections showed much pluriglandular infiltration. The cylindrical epithelium of the mucous membrane was invariably unbroken, either in the canal or in the glands opening into it.

311 Menstruation and Epilepsy

According to A. SOUQUES (*Presse Méd.*, February 7th, 1931, p. 185) menstruation and epilepsy are interrelated, but only under two conditions: when the crises appear for the first time between puberty and the menopause and when they recur during a variable length of time in synchronism with the menstrual periods, or the times at which menstruation should occur. In the first category menstruation and the crises coexist; in the second the catamenia are absent, and are replaced by epileptic seizures. Many cases reported in the literature and cited by Souques indicate that there is an actual, and not fortuitous, relationship between the two conditions, and that menstruation (as well as other states, such as pregnancy and the menopause) exerts both a favourable and an unfavourable influence on the epilepsy. Further proof of this relationship is afforded by the benefits resulting from the administration of the follicular hormone. The pathogenesis of menstrual epilepsy is unknown, but two theories about its causation have been advanced: that it is a reflex phenomenon, or is due to a humoral disturbance. Souques reviews the physiology of menstruation and discusses these theories. He suggests as the most probable cause the existence of a previous histological or biological alteration of the nervous centres together with a humoral disturbance—that is, an intoxication which, when a certain degree of concentration is reached; excites the nerve cells, either directly or indirectly through the vago-sympathetic system, and thus the epileptic crisis is caused.

312 Treatment of Placenta Praevia

C. H. PECKHAM (*Amer. Journ. Obstet. and Gynecol.*, January, 1931, p. 39) deprecates the indiscriminate routine employment of Caesarean section in placenta praevia; although the chances of the child are increased by this procedure, there would be little or no reduction in the maternal mortality rate. Many of the patients who succumb are too ill on admission to hospital or are bleeding too severely to warrant the added risk of laparotomy. Others, in consequence of previous infection by unskilful examinations or the introduction of vaginal packs, would be considerably endangered by Caesarean section, unless followed by hysterectomy. The author considers, however, that section is indicated in cases of central placenta praevia when the patient is admitted to hospital before labour has begun, or when it is still in a quite early stage, the child being alive. In the marginal type of implantation the hydrostatic bag is thought by Peckham to offer the best results. His conclusions are based on the study of 146 cases of placenta praevia occurring in a series of pregnancies numbering 36,198. He believes that the still high maternal mortality figure (8.64 per cent.) could be reduced by more prompt hospitalization and the more frequent employment of transfusion. The incidence of premature labour in this condition is high, but the maternal mortality in such cases is low, increasing more than three times when delivery occurs at or near term.

Pathology

313 The Relation of Vitamin D to Irradiated Ergosterol

A. D. HOLMES (*New England Journ. of Med.*, January 29th, 1931, p. 211) suggests that vitamin D and irradiated ergosterol may be one and the same substance. The data upon which this conclusion is based were obtained from experiments with laboratory animals, from clinical studies, and from laboratory studies of the chemical nature of irradiated ergosterol. These data seem to indicate that, for the treatment of rickets, either vitamin D, as it occurs in cod-liver oil, possesses properties not present in irradiated ergosterol, or that the vitamin A or some other substance in cod-liver oil enhances the antirachitic vitamin in the oil, so that it is more effective in the treatment of rickets than equivalent rat units of irradiated ergosterol. The early studies of the chemistry of irradiated ergosterol indicated that this material was quite similar chemically to vitamin D; both were soluble in fat or oil, both were destroyed by oxidation, both lost their antirachitic value when subjected to prolonged irradiation, and neither was destroyed by saponification. Recent work (Bills) has shown that there are many isoergosterols and that certain of these are convertible into each other. A comparison of activated ergosterol and cod-liver oil involves a consideration of isomerism, and it would appear that their antirachitic action is not identical, cod-liver oil appearing to be greatly superior to irradiated ergosterol.

314 Undulant Fever Investigations in Germany

F. WEIGMANN (*Deut. med. Woch.*, February 13th, 1931, p. 284), working at Kiel, examined 3,535 specimens of serum between the end of January, 1928, and the end of August, 1930. Of these, 119 agglutinated *Br. abortus* to a titre varying from 1 in 50 to 1 in 20,000, the commonest titre being 1 in 1,000 to 1 in 5,000. Blood cultures were put up in 72 cases, but in only five instances was the causative organism recovered, even though an atmosphere of 10 per cent. CO_2 was maintained during incubation. Details were available concerning 91 of the reacting patients. In the majority of these there was a history of undulant, remittent, or intermittent fever, with a slow pulse, subjective well-being even with a high temperature, leucopenia with a relative lymphocytosis, and frequently a complete absence of physical signs, though splenic swelling, epididymo-orchitis, endocarditis, bronchitis, diarrhoea, or constipation, and joint pains and swellings were sometimes met with. In 4 patients giving a positive serum reaction the fever appeared to be due either to typhoid fever or to croupous pneumonia; in two other patients a mixed infection was present. Five persons were detected on farms who gave a positive serum reaction without any history of illness. The author considers that these persons were suffering from a latent infection. Such a condition he regards as being fairly common; he points out that quite frequently the onset of undulant fever follows some other illness or may apparently even be determined by a fracture, suggesting that a fall in the resistance of the body may allow a latent infection to become manifest. In 49 of the cases milk was probably the source of infection, in 7 cases contact with infected cattle, in 20 cases both sources of infection were available, and in 15 cases no definite evidence was forthcoming. As regards sex, there were 85 men and 34 women. The youngest patient was 11 years old and the oldest 75 years, the commonest age being 20 to 40 years. The author thinks that the disease would be found in children if only a systematic examination was made of the blood serum in all doubtful cases of febrile illness.

315 Pathogenic Factors in essential Pernicious Anaemia

G. FONTÈS and L. THIVOLLE (*C. R. Soc. de Biologie*, January 30th, 1931, p. 219) have previously reported that a deficiency in the two amino-acids tryptophane and histidine causes grave troubles, among which is a change in the blood picture. They believe that pernicious anaemia may be caused by a deficiency of this kind, and advance the following arguments in support of this opinion. Though achlorhydria is usually considered the cardinal symptom of this disease, the pancreatic and intestinal juices have normally a diastasic activity, and functional failure of all the digestive diastases may occur in pernicious anaemia. From the imperfectly peptonized albumins produced in cases of achlorhydria the digestive juices with difficulty produce the amino-acids which normally bring about the nitrogenous replenishment of the organism. Moreover, tryptophane and histidine are highly sensitive to intestinal bacterial action; these organisms are abundant in pernicious anaemia. Such facts, together with the loss in weight, point to a total or partial chronic deficiency in these substances. The success following hepatotherapy in this disease is ascribed by the present authors to the fact that the liver contains the amino-acids formed during digestion. Finally, daily subcutaneous injections of tryptophane (100 mg.) and histidine (200 mg.) have produced marked benefits in pernicious and splenomegalic anaemias, and in leukaemia. The authors suggest that this may prove an efficient treatment in cachectic diseases.

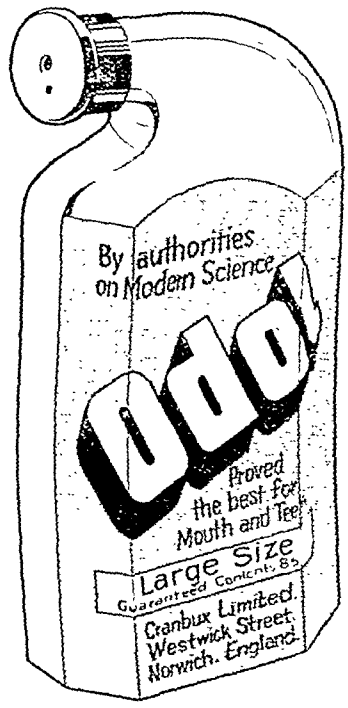
Odol

A STRONGLY ACTING ANTISEPTIC

Anti-Acid, Non-Caustic, Non-Toxic.

"I find ODOL a most agreeable preparation, combining the qualities of an efficient and purifying medium with the penetrating power of a strongly acting but innocuous antiseptic solution, and meeting in this way the greatest desiderata in the hygiene of the mouth."

Signed . . . M.B., Ch.B.
(Didsbury, Manchester.)



ODOL will actually destroy Bacillus Typhosus within 30 seconds if used at a strength of 4%.

Samples and literature will gladly be sent to any member of the Medical profession on application to:

C.R.4151. — PERSONAL WEIGHING MACHINE. Height 10 in. Can be stowed away under couch. Enamelled Green or Black. Weighs accurately to 20 stone £3 3 0

Stand for Ditto, raising machine to seat level, extra £1 5 0

S.P.1040.—Basket to fit in platform of machine illustrated for weighing Babies. 10/6 extra.

MOST SUITABLE FOR CLINICS.

Fig. C.R. 1645.—Bailey's Perfection Consulting Room Couch, handsome, strong, and best finish throughout, solid Mahogany, Oak, or Walnut frame, Upholstered hair and best Rexine Leather Cloth, buttoned or plain (any colour Rexine). Adjustable, and can instantly be converted into a chair for throat, nose, and ear examinations.

£10 15 0 Carriage Paid, England.

Detachable Leg Section extra 15s. Leg Crutches and Sockets extra 36s.

Surgical Instruments and Appliances - 45, OXFORD STREET,
Hospital and Invalid Furniture - - 2, RATHBONE PLACE, } **LONDON, W.1**

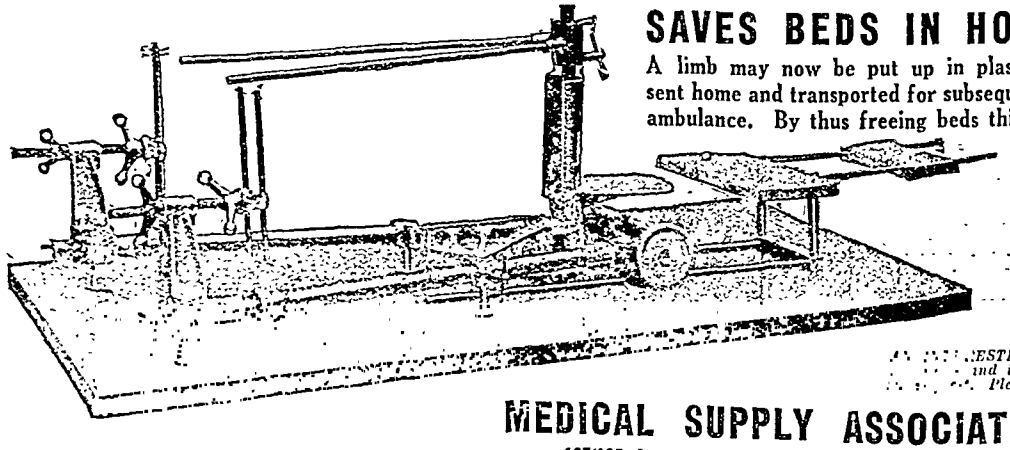
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

INTERESTING LEAFLET giving full particulars and instructions, post free on application. Please ask for a copy.

ALIMENTARY TOXAEMIAS

PUTREFACTIVE bacteria increase in numbers in the intestine as age advances. They are relatively scanty in the young child, but after middle life are usually present in considerable numbers. Of the micro-organisms concerned, proteolytic anærobes are probably the most important.

In individuals with a normal intestine and free evacuations, they may do little harm, but in those subject to intestinal catarrh, these putrefactive bacteria become more numerous and active, their products are formed in greater quantity, and are more freely absorbed, and the condition of alimentary toxæmia results. The manifestations of this state are very protean, *e.g.*, "rheumatic" conditions, digestive upset, neurasthenia and neuralgias, increased blood pressure and its complications, and many others. The treatment, in the first place, obviously should be *intestinal disinfection*. For this purpose nothing surpasses the use of KEROL CAPSULES. They have solved for years the question of disinfection of the alimentary tract. They definitely reduce the bacterial content of the intestine, as shown by the reduction in *B. coli* by 99% when the capsules are regularly administered for a period of from seven to ten days.

We have from time to time published several booklets containing clinical evidence as to their value, and these we will gladly forward, on receipt of a postcard, to any member of the Medical Profession.

The Ideal Laxative

REGULOL

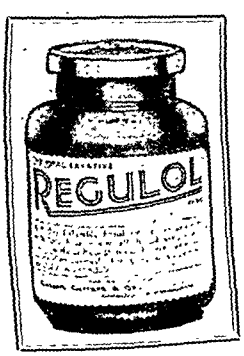
REGD.

"REGULOL" IS AVAILABLE IN TWO FORMS: "PLAIN" or "COMPOUND." The latter is a combination with Phenolphthalein 4 grains per oz., and is indicated in more acute forms of Constipation where the simple lubricating effect of Paraffin is insufficient.

CUXSON, GERRARD & Co., Ltd.
Oldbury, *Birmingham.*

IT is a highly palatable Emulsion of Liquid Paraffin with Agar-Agar, possessing all the advantages of the former without its objectionable qualities, and forming probably the best possible remedy for Chronic Constipation in Children and Adults.

SAMPLE 1-lb. JAR FREE ON REQUEST.
Please indicate whether Plain or Compound is required.
(This offer is limited to the British Isles.)



"TRILACTINE"

(R.T.M.)

A good Lactic Acid Bacillus Preparation for the treatment of

CONSTIPATION, COLITIS,

and many intestinal infections.

"Trilactine" Tablets for taking with sugar, or for making curdled milk at home, are supplied in boxes of 48, 4/-.

W. MARTINDALE, 12, New Cavendish Street, LONDON, W.1.

Telephone: LANGHAM 2440. Telegrams: "MARTINDALE, CHEMIST, LONDON."

The Biological Significance of BOVRIL

BOVRIL combines the nutritive proteins of beef with its stimulant and body-building extractives. The beneficial effect of Bovril upon a weakened constitution is therefore of a permanent nature. It helps the patient not only to gain strength but also to consolidate it.

ANTISEPTIC CREAM

(Hewlett's)

An emollient healing cream for BLEPHARITIS, ACNE, ECZEMA, and all abrasions and irritation of the Skin.

Its soothing and healing properties are most marked.

In enamelled collapsible tubes, 18s. doz., or 1-oz. pots, labelled only "The ointment to be used as directed," 10s. 6d. doz.

In bulk, 5-oz., 10-oz., 22-oz., 40-oz., 4½ lb. & 7½ lb. pots, 5s. 6d. lb.

Introduced and Prepared only by

C. J. HEWLETT & SON, Ltd., 35 to 42, Charlotte Street, London, E.C.2

"STERULES" *Regd.*

Some Unsolicited Appreciation

Dear Sirs,—I beg to thank you for the best stethoscope I ever used, and during the last forty years I have used a good many.
Yours faithfully, ——

Dear Sirs,—I find that most certainly the chest sounds are rendered clearer and more distinct by your "Phonophore" than by any Stethoscope I have used during over thirty years' work.—Yours faithfully, ——

Dear Sirs,—I find your "Phonophore" indispensable. Being more or less deaf, without it I should be compelled to relinquish practice. With it I can hold my own.
Yours faithfully, ——

Dear Sirs,—The "Phonophore" is extremely satisfactory and far superior to any stethoscope I have used.
Yours truly, ——

Makers of Superior Surgical Instruments and Appliances.

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS

arranged for Doctors and Patients.

Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.

Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.

There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.

Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

SUCCESSFULLY PRESCRIBED FOR MANY YEARS

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, *persons suffering from incipient nervous and mental disorders*, as well as certified *patients* of both sexes, are received for treatment. *Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female*, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various *methods, including* Turkish and Russian *baths*, the prolonged immersion bath, *Vichy* Douche, Scotch Douche, Electrical bath, Plombières *treatment, etc.* There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for *Diathermy* and High *Frequency* treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two *miles* from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.
Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

A copy of the regulations governing the Scholarship can be obtained from the undersigned, to whom six copies of application should be sent not later than Saturday, April 18th.

FRANK G. HAZELL,
Manchester Royal Infirmary. Secretary to the Trustees.

Manchester Royal Infirmary.

Applications are invited for the DICKINSON RESEARCH SURGERY SCHOLARSHIP, value £75, tenable for one year. Candidates must be University Graduates who have taken out the full course of Clinical Instruction in the Manchester Royal Infirmary.

A copy of the regulations governing the Scholarship can be obtained from the undersigned, to whom six copies of application should be sent not later than Saturday, April 18th.

FRANK G. HAZELL,
Manchester Royal Infirmary. Secretary to the Trustees.

Manchester Royal Infirmary.

CENTRAL BRANCH, RORY STREET, MANCHESTER.

HOUSE SURGEON (Lady).

The Board of Management of the Manchester Royal Infirmary invite applications for the above appointment.

Applicants must be registered and hold a Medical and Surgical qualification.

The appointment is tenable for nine months commencing May 1st—three months as Junior at £100 per annum, three months as Assistant at £100 per annum, and three months as Senior at £200 per annum, together with board and allowance for laundry.

Applicants must state age and qualifications, and send twelve copies of their applications and testimonials to the undersigned by 9 a.m. on Thursday, April 9th.

By Order,
FRANK G. HAZELL,
Gen. Supt. & Secretary.

University of Bristol.

The University invites applications for a LECTURESHIP IN PHYSIOLOGY. Salary £300 to £400 per annum, according to qualifications.

St Mary's Hospital, Manchester

Two HOUSE SURGEONS for the WHITWORTH ST. WEST HOSPITAL (Maternity), and Two for the WHITWORTH PARK HOSPITAL (Gynæcological), each for a period of six months from May 1st next. Salaries at the rate of £50 per annum, with board and residence. Applications, with copies of three testimonials, to be sent to the undersigned on or before April 16th.

R. RATCLIFFE, Secretary.

Shanghai Municipal Council

PUBLIC HEALTH DEPARTMENT.

ASSISTANT PATHOLOGIST.

An additional Assistant Pathologist is required in the Public Health Department of the Shanghai Municipal Council.

Candidates, preferably unmarried, should not be more than 30 years of age, and must hold qualifications in Medicine and Surgery of University standard. In addition, they must have working experience of the routine of a Pathological Laboratory, and practical knowledge of the manufacture of bacterial vaccines in bulk is desirable. Experience in Tropical Medicine would be a recommendation.

Salary for three years, Taels 650 per mensem, or Taels 700 per mensem if holding a D.P.H. or its equivalent. Thereafter rising by triennial increments of Taels 100 to Taels 1,250 or Taels 1,300 if with D.P.H., subject to satisfactory service. After six years on the maximum pay, a final long service increase of Taels 100 per mensem is granted. A Tael at the present rate of exchange equals about 1/4d. Exchange is, however, subject to fluctuation.

Service is under Letter of Appointment, which is for three years in the first instance.

Owing to the present adverse exchange rates the Council, under certain limitations, guarantee one-third of pay at the rate of 2/6 to the Tael. Further particulars may be obtained on application.

First-class passage is provided, with half-pay during the voyage, and 7 months' leave is given on full pay, with first-class passage, after every period of 5 years' service in Shanghai.

Free Medical attendance and Hospital accommodation in accordance with the Council's standard rates are provided, and there is participation in the benefits of a Superannuation and Pension Fund.

Full particulars of the vacancy and the Terms of Service in force for Municipal employees may be obtained from the Council's Agents.

Applications, with full information as to qualifications, experience, &c., accompanied by three recent testimonials and endorsed "Assistant Pathologist," should be forwarded to the Council's Agents, Messrs. JOHN POOK & COMPANY, 68, Fenchurch Street, London, E.C.3.

March, 1931.

City of Cardiff.

CITY LODGE INSTITUTION.

SECOND AND THIRD ASSISTANT MEDICAL OFFICERS.

Applications for the above appointments are invited from duly qualified unmarried Medical Men or Women, who must devote their whole time to the duties, reside in the Institution, and (subject to the Public Assistance Order, 1930, and the Orders of the Council) act under the direction of the Medical Officer of the Institution.

The salary of the Second Assistant will be at the rate of £490 per annum, rising by yearly increments of £25 to £590 a year. The person appointed, if not a transferred officer paying Superannuation contributions under the Poor Law ... Act, 1896, will be required to contribute ... per cent. of his or her salary under the Superannuation Scheme of the Council, and for this purpose to pass a medical examination, and will be provided with board, lodging, attendance, and washing, for which he or she will pay the sum of £140 a year.

The position of Third Assistant will be tenable for one year only, and the salary will be at the rate of £150 per annum, with board, lodging, attendance, and washing.

Assistant Medical Officers are liable to be called upon by Justices to examine and certify persons alleged to be of unsound mind. Any fees payable in respect of such examinations and certificates or for recommendations under the Mental Treatment Act, 1930, and any fees payable for vaccination, must be returned to the Council.

Applications on forms to be obtained from the Public Assistance Officer, 11, Park Place, Cardiff, from whom further information may be obtained, must reach me by 5 p.m. on Wednesday, April 8th.

Direct and indirect canvassing is prohibited.

CECIL G. BROWN,
Town Clerk.

County of Kincardine.

DEPUTE MEDICAL OFFICER OF HEALTH.

Wanted by the County Council of the County of Kincardine, a Depute Medical Officer of Health. Commencing salary £600. For conditions of appointment apply to the County Clerk, Stonehaven, with whom applications (18 copies), giving full particulars of age, qualifications and experience, and testimonials (18 copies of each), must be lodged by April 18th.

County Council of Durham.

EARL'S HOUSE SANATORIUM.

MEDICAL OFFICER.

Applications are invited for the post of Medical Officer of Earl's House Sanatorium for Boys, near Durham, which has accommodation for about 80 patients.

The salary will be at the rate of £450 per annum, rising by annual increments of £25 to £500 per annum, together with furnished quarters and board, etc., valued at £150 per annum, in addition. In the case of a married man the emoluments will be paid in cash, as there is accommodation (a cottage) for which a charge of £50 per annum is made by the County Council to cover rent, rates, electric light, and water.

The officer appointed must be a registered Medical Practitioner, and must devote whole time to the duties required of such person by the County Council, including part-time services as an Assistant Tuberculosis Medical Officer. It is essential that the person appointed shall have held House appointments in a General Hospital, and have had practical experience in the administration of a Tuberculosis Sanatorium and in the treatment of tuberculosis in such an institution, and in Bacteriological work. Experience in ultra-violet ray treatment and X-ray technique will also be necessary.

The person appointed will be attached to the County Health Department, and will be required, subject to the control of the County Medical Officer of Health, to take full responsibility for the general management of the Institution, including the supervision of the staff and the treatment of patients.

The appointment will be terminable by three months' notice on either side. A deduction of 5 per cent. will be made from the salary in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to the successful candidate passing the County Council's medical examination in connection therewith.

Applications, endorsed "Medical Officer, Earl's House Sanatorium," with copies of not more than three recent testimonials, must be delivered to the County Medical Officer, Shire Hall, Durham, on or before April 4th.

Shire Hall, Durham. HAROLD JEVONS, Clerk of the County Council.

March 16th, 1931.

Administrative County of Essex.

JUNIOR ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

The County Council of the Administrative County of Essex invite applications for the above post from registered Medical Practitioners holding a Diploma of Public Health, and not over 45 years of age.

Preference will be given to candidates who have had at least three years' experience in Public Health work subsequent to their medical qualification. The salary attached to the appointment will be £500 per annum, and will rise by annual increments of £25 to £700 per annum. Travelling expenses will be paid by the Council.

The person appointed will be required to devote his whole time to the service of the Council, and to perform such duties and to furnish such advice and assistance appertaining to his office as may be required, and to reside in such district of the County as the Council may decide. The appointment will be subject to three months' notice on either side.

The person appointed will be required to pass a medical examination, and to contribute 5 per cent. of his salary to the fund established under the Local Government and Other Officers Superannuation Act, 1922.

Applications, on the prescribed form, obtained from the undersigned, and accompanied by copies of not more than three testimonials, which will not be returned, should be addressed to me and delivered at the Shire Hall, Chelmsford, not later than 10 a.m. on Monday, April 6th.

Shire Hall, Chelmsford. JOHN H. GOOLD, Clerk of the County Council.

March 16th, 1931.

The Radium Institute,

Riding House Street, London, W.1.

Applications are invited for the post of Whole-time RESIDENT SURGICAL REGISTRAR (male). Candidates must be unmarried.

The salary will be at the rate of £250 per annum, board, residence, and laundry being provided, and the appointment is for six months commencing May 1st next.

Applications, stating age, nationality, qualifications, and experience, with copies of three recent testimonials, must be received at the Institute on or before April 6th next.

Canvassing, either directly or indirectly, is not permitted.

THOS. A. GARNER, Secretary.

Surrey County Council.

COUNTY SANATORIUM, MILFORD, SURREY. (300 Beds.)

Applications are invited from qualified and registered Medical Practitioners for the post of THIRD ASSISTANT RESIDENT MEDICAL OFFICER at this Sanatorium.

Candidates should be under 35 years of age and have held resident Hospital appointments. Sanatorium experience is not essential.

The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination. The appointment will be made in the first instance for a period of six months, renewable at the end of that period for a further six months. Termination of engagement will be at one month's notice on either side.

The salary is £350 per annum, together with board, lodging, and laundry. These emoluments are valued at £100 per annum for purposes of superannuation.

The successful candidate will be required to devote his whole time to the services of the County Council.

Forms of application may be obtained from the County Medical Officer of Health, County [illegible] to whom completed returned, together t testimonials, not later than Saturday, April 4th.

DUDLEY AUKLAND,
Clerk to the Surrey
March 11th, 1931. County Council.

Borough of Twickenham.

ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified Medical Practitioners (men or women) for the appointment of Assistant Medical Officer. The work will include duties connected with Maternity and Child Welfare, School Medical Inspection and Treatment, and the Borough Hospital for Infectious Disease.

Special experience of Ante-natal and Maternity and Child Welfare work is obligatory, and the possession of a Diploma in Public Health will be an additional recommendation.

Salary £550 per annum, rising by annual increments of £25 to £700.

The successful candidate must pass a medical examination before appointment, and application will be made for the post to be designated under the Local Government and Other Officers Superannuation Act, 1922. The officer will be required to work under the direction and supervision of the Medical Officer of Health; to devote whole time to the service of the Corporation, and to reside within the Borough of Twickenham.

A form of application can be obtained from the Medical Officer of Health, Dr. G. H. DUPONT, Municipal Offices, Twickenham, to whom applications, accompanied by copies of not more than three recent testimonials, are to be sent by April 1st.

Municipal Offices, EDWIN G. STRAY,
Twickenham. Town Clerk.

APPOINTMENTS.—Contd.

Administrative County of LONDON.

HOSPITAL SERVICE.

The LONDON COUNTY COUNCIL invites applications from duly qualified Medical Practitioners for appointment to the undermentioned positions. Salary in each case £350 a year, rising by annual increments of £25 to a maximum of £425 a year, together with board, lodging, and washing. Candidates must have held a Resident appointment in a General Hospital for at least six months. The successful candidates will be required to live in the respective Hospitals.

ST. MARY ABBOT'S HOSPITAL, Marloes Rd., Kensington, W.8. — ASSISTANT MEDICAL OFFICER (woman only). The person appointed will be required to carry out such duties as may be assigned by the Medical Superintendent, and, if required, to assist at the Institution or in medical districts under the control of the Hospital. The duties are mainly Medical, with some Maternity work. Marriage terminates contract of service.

ST. MARY, ISLINGTON, HOSPITAL, Highgate Hill, N.19.—ASSISTANT MEDICAL OFFICER. The person appointed will be required to carry out such duties as may be assigned by the Medical Superintendent, and, should occasion arise, to assist at any of the other establishments or medical districts under the control of the London County Council. Surgical experience is essential. There is no accommodation for a married man or for a woman.

Forms of application may be obtained (stamped addressed foolscap envelope necessary) from the Medical Officer of Health (Staff Division S.D. 4a), The County Hall, Westminster Bridge, S.E.1, and must be returned by April 10th. Canvassing disqualifies. Inquiries for further details as to nature and scope of duties should be addressed to the Medical Superintendents at the respective Hospitals.

MONTAGU H. COX,
Clerk of the London County Council.

St. John's Hospital for Diseases OF THE SKIN, 49, Leicester Square, W.C.2.

Applications for the post of JUNIOR HONORARY MEDICAL REGISTRAR (male or female) are invited to be sent to the undersigned on or before Monday, March 30th. Honorarium £50 per annum.

Applicants must be duly qualified and registered Medical Practitioners. Particulars of the duties can be obtained on application.

LEONARD G. R. TURPIN,
Secretary.

Scunthorpe and District War MEMORIAL HOSPITAL.

Applications are invited for the post of a Second Resident (male) as HOUSE PHYSICIAN, to take up duties as early as possible. Salary at the rate of £150 per annum, with board, residence, and laundry. Candidates, who must possess registered qualifications, should forward applications, stating age, nationality, etc., together with copies of recent testimonials, to—

ARTHUR E. MAW, Secretary.

London Jewish Hospital, Stepney Green, E.1.

(General Hospital—108 Beds.)

The Council of Management invite applications for the appointment of HONORARY ASSISTANT PHYSICIAN, who will be required to make two Out-patient visits weekly. Only one session (Wednesday afternoon) is available at present, but the second will be allotted when occasion arises.

Candidates must possess the degree of M.D. or M.B., obtained by examination at a recognised University, and be Fellows or Members of the Royal College of Physicians of London, or Fellows of the Royal College of Physicians of Edinburgh or Ireland, and shall not be engaged in the practice of Pharmacy or Midwifery.

Candidates must send twenty copies of their application, with copies of three recent testimonials, to the Secretary of the Hospital, on or before Friday, April 17th.

City of Birmingham.

MATERNITY AND CHILD WELFARE DEPARTMENT.

CITY BABIES' HOSPITAL. (85 Beds.)

A JUNIOR RESIDENT MEDICAL OFFICER is required on June 1st for a period of six months. Previous experience as a Resident Medical Officer in a Children's Hospital or in a General Hospital is desirable. Salary at the rate of £100 per annum, with board and laundry.

Apply, giving all particulars of qualifications, age, and experience, to the Medical Officer of Health, Council House, Birmingham, on or before April 11th.

City of Birmingham.

MATERNITY AND CHILD WELFARE DEPARTMENT.

Three Temporary MEDICAL OFFICERS are required from July 3rd to September 30th (approximately), and a Fourth Temporary MEDICAL OFFICER from July 1st to September 2nd. Applications are invited from ladies who have had Obstetrical experience and an appointment in a Children's Hospital. The salary offered is £10 per week.

The appointment cannot be terminated within the period named, except for health reasons.

Applications should be sent on or before April 11th to the Medical Officer of Health, Council House, Birmingham.

Liverpool Stanley Hospital.

Applications are invited for the post of HONORARY SURGEON.

Applications, with qualifications and testimonials, addressed to the President, to be sent on or before Saturday, April 18th.

The canvassing of any member of the Election Committee will disqualify, but candidates are at liberty to send to the members copies of their applications and testimonials.

FRANK WHITE, Hon. Secretary.

Liverpool Stanley Hospital, Stanley Road, LIVERPOOL.

Wanted at once, One Male HOUSE PHYSICIAN and One Male HOUSE SURGEON to commence duty on April 1st. SAVED BABY'S LIFE!

PORTE'S CAESAREAN OPERATION

In 'The Scottish Nurse' for January 1931 appeared an article by a Scottish State-Registered Nurse describing an exceedingly severe operation—*Porte's Caesarean Section*—which she underwent in Malta at the hands of a well-known surgeon.

Twenty-four hours after the second stage of labour had begun it was discovered that delivery was impossible. The womb had become septic and the Porte Caesarean was performed, the baby being safely extracted.

The condition of the mother was then highly critical, and the baby had to be revived by artificial respiration. For a week after birth she weighed only five pounds. The mother, despite intense pain and weakness, endeavoured to nurse her, but as progress appeared stationary she was put on alternate feeds of Cow & Gate Full Cream Milk Food and Breast.

From then onwards she made rapid progress and at four months the mother weaned her altogether.

Now eight months old, the child is the picture of contentment and happiness and weighs over 17 pounds.

COW & GATE MILK FOOD

has saved more baby lives than any other preparation in the world

EDWENIL:

A POLYVALENT NATURAL ANTIBODY

FOR BACTERIAL INVASIONS OF AN ENDOTOXIC NATURE

in FURUNCULOSIS

Whether there be a single boil or a multiplicity of furuncles, subcutaneous injections of Edwenil will produce a prompt response.

If treated in the early stages, the boil or furuncle disappears without coming to maturity. In more mature lesions the growths quickly come to a head, burst, and there follows a rapid recovery.

The time required for the complete resolving of even an extensive carbuncle is interestingly short.

Similar results have been obtained in long-standing cases of acne, where other forms of treatment, including X-Ray and Ultra-Violet Ray, had failed.

FOR PROMPT RESULTS IN COLDS AND INFLUENZA USE EDWENIL.

Obtainable in 25 c.c. Bottles.

MADE ONLY IN THE LABORATORY OF

E. H. SPICER & CO., LTD.,

Greater Comfort for your Patients.

"The Rose Corset-Belt"

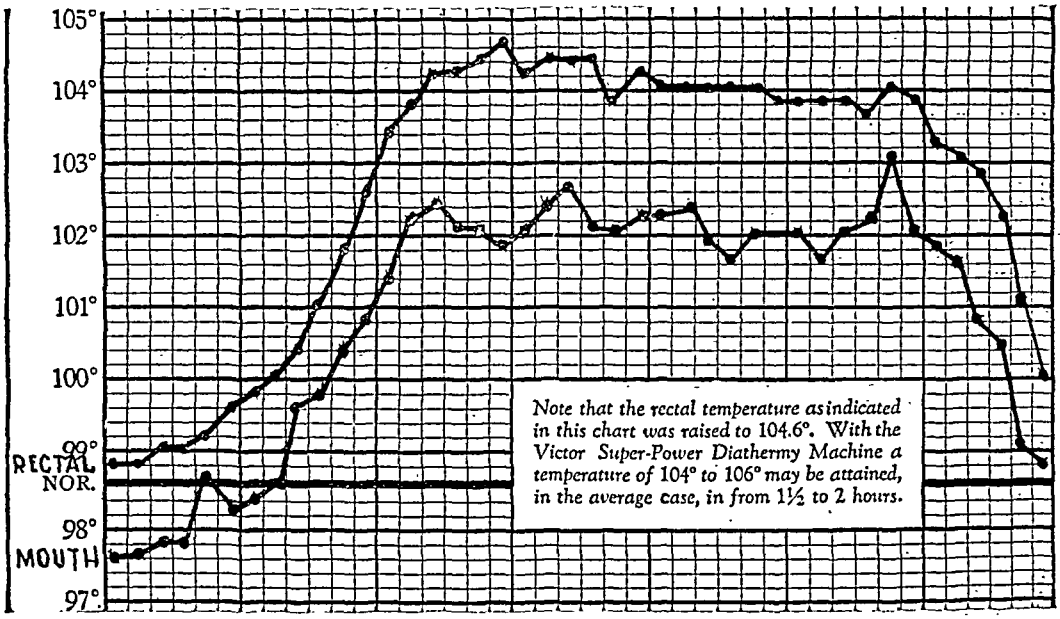
which has set a new standard and proved so effectual in all abdominal cases where support is required. The X-rays have shown the actual uplift.

Each Corset-Belt is cut and fitted to individual requirements, and the patient is kept under observation until every satisfaction is given to both patient and doctor.

I have also invented an improved Colotomy Belt for both male and female patients.

My work is recommended by eminent members of the medical profession, and the following hospitals: St. Bartholomew's Hospital, Metropolitan, Charing Cross, Middlesex, London Temperance.

MADAME ROSE, 97, Mortimer St., Regent St., W.1. LANGHAM 1575.



Therapeutic Fever is Produced *quickly with Diathermy*

THROUGH the courtesy of Dr. C. A. Neyman of the Northwestern University Medical School, we are permitted to reproduce the above chart, as typical of cases in which fever has been produced by means of the diathermy current.

In the treatment of paresis and other forms of afebrile diseases, investigators in this form of therapy have found the use of diathermy to give very gratifying results, offering definite advantages over the method of injection of pathogenic organisms and the attendant uncertainty of their secondary effects. With diathermy the physician has accurate control of the frequency, duration and intensity of the fever.

The Victor Super-Power Diathermy apparatus has a power output considerably greater than that of any other diathermy apparatus, and a refinement of control that assures the most practicable method of application in this form of therapy.

Upon request we will be glad to send reprints of articles pertaining to the production of artificial fever with diathermy, together with description of the Victor Super-Power apparatus.

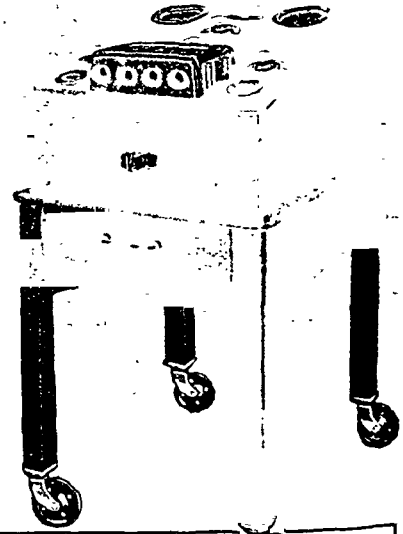
VICTOR

Telegrams: "STABILIZER"



The Victor Super-Power Diathermy Apparatus

Will give as much current as any patient can tolerate through the chest and abdomen with the largest sizes electrodes used thus far in this work.

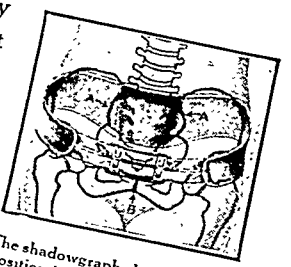
With a control system which permits the selection of both frequency and voltage, the quality of current desired is quickly available. This refinement of control applies throughout the range of the machine. Thus it serves every purpose of diathermy known to medical science up to the present.

For the Relief of Sacro-iliac Relaxation or Strain.

WHEN a sacro-iliac lesion has been caused by heavy lifting, child-birth, bad posture or other conditions, a Spencer Belt relieves the condition by immobilizing the articulations involved.

Fixation of the sacro-iliac joints is achieved by means of a Spencer specially designed belt or corset whose inner band, fitted with a pad, acts as a fulcrum in securing proper adjustment.

The sacro-iliac band which is built inside the corset or belt can be adjusted as tightly as necessary from the outside after the belt or corset is in place. Since the band is built into the Spencer Support, it never rides out of position. It holds the bony structure in position, thus relieving tension or pressure and hastening the return to normal condition. Each Spencer Support is especially designed for the patient who is to wear it. The Spencer Corsetière in your town will call at your Surgery or at your patient's home to take measurements under your supervision. Spencer Supports and Corsets are never sold in shops.



The shadowgraph above shows the position in which the special inner belt is applied to the body. This is not a complete garment worn by itself but a part of a Spencer Sacro-iliac Corset or Belt which holds it in position.

KEROL CAPSULES

COMBATS RHEUMATISM BY BANISHING AUTO-INTOXICATION

The prevalence of such maladies as rheumatism, lumbago and neuritis is now generally recognised as being, in many cases, directly attributable to auto-intoxication arising from constipation. Sal Hepatica is a proved, medicinal, effervescent saline which stimulates the bowels to peristaltic action ensuring the elimination of all toxic waste products. Its sodium phosphate content increases the secretion of bile, thus restoring the daily habit of defecation by natural means. Unlike many other laxatives therefore increasing dosage is unnecessary. Sal Hepatica does not cause depression, griping or weakness.

Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol Myers Company.

MALNUTRITION and MARASMUS

Mellin's Food when given in conjunction with cow's milk and water produces an immediate gain in weight in fermentative dyspepsia and in wasting disorders of early infancy. For the prematurely born infant Mellin's Food proves invaluable.

As is well known, sugars exhibit varying tendencies to fermentation in the digestive organs. Milk sugar ferments most rapidly, less rapidly cane sugar, and maltose still more slowly, and the high percentage of dextro-maltose in Mellin's Food accounts for its usefulness in all such cases of malnutrition.

Mellin's Food

The booklet "Modified Milk in Infant Feeding" deals fully with the use of Mellin's Food in cases of malnutrition, and will be gladly sent together with samples to Members of the Medical Profession.

Medisoap

MIDGLEY'S MEDICATED SOAP Regd

The word MEDISOAP is a registered trade-mark indicating the pure soap base made and scientifically medicated by CHARLES MIDGLEY, LTD., according to published formulae. This method of skin medication has been brought into favour by the ease with which applications can be made and the certainty of absorption through regularity of use by the patient.

A PRESCRIBER'S INDEX relative to the comprehensive range of Medisoaps is available to members of the medical profession on application to EVANS' BIOLOGICAL INSTITUTE, RUNCORN.

Medisoap Depots all over the country.

Sole Makers:

ACNE

As an adjuvant in the treatment of this condition there are a number of Medisoap formulae recommended by many practitioners, and patients prefer this treatment to the disfiguring effects of ointments.

MEDISOAP No. 18, containing Naphthol 2½% and Sulphur 10%, used with success in Acne Vulgaris.

MEDISOAP No. 39, containing Ichthamol 5%, Ac. Salicyl 2½%, recommended in Acne Rosacea.

MEDISOAP No. 15, containing Ichthamol 5%, Pix Liquida 5%, is another popular formula.

For further particulars see *"Prescriber's Index."*

CHARLES MIDGLEY, LTD. Medicated Soap Specialists MANCHESTER

Associated with EVANS SONS LESCHER & WEBB, LTD., Liverpool, London, and Dublin.

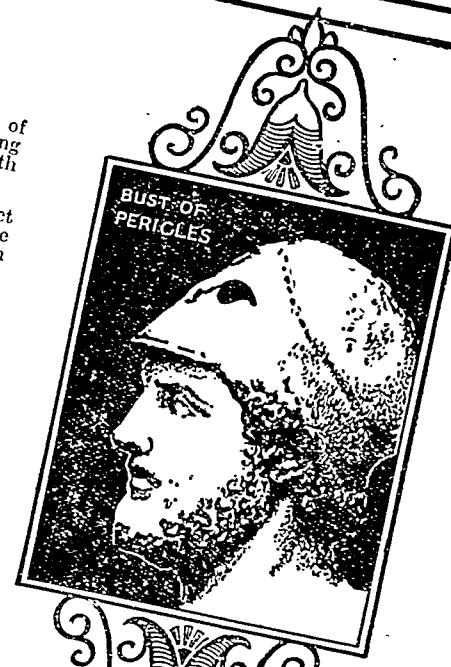
Bowel Inertia

THE Physician is familiar with the patient who complains of headache, loss of appetite, depression, who is not suffering pain but is nevertheless conscious that his or her general health is far below the standard it should be.

Diagnosis often reveals auto-intoxication—the result of habitual constipation. The use of a suitable eliminant is indicated.

"Cristolax" proves exceptionally successful in such cases. It is composed of 50% of the purest medicinal paraffin in combination with 50% "Wander" Dry Malt Extract. The high diastasic quality of the pure malt extract gives material assistance to the digestive process which is often impaired in this condition, whilst the oil content lubricates the intestinal tract, keeps the faeces soft, and ensures their complete expulsion.

A delicious preparation in a clean, convenient dry form for infants, children, and adults.



"CRISTOLAX"

. . . made to the original formula MARSHALL'S LYSOL

The surgeon whose instruments are sterilised in a dilution of MARSHALL'S Lysol uses them with absolute confidence. The physician who knows his nurses use it in dressings and antiseptic work has an easy mind, where the dread of 'infection' need never intrude.

MARSHALL'S Lysol is made to the original Lysol formula and specification. Every bottle is tested for purity and strength.

Samples will be sent upon request to members of the medical and nursing professions.

Lysol Ltd., Raynes Park, S.W.20

SAFE

Symptomatic relief in 5 minutes

THE symptoms of common cold—congestion, discharge and obstructed breathing—are frequently distressing. From the patient's point of view, they constitute the essence of the annoyance from which he is seeking immediate relief.

Rapidity of action is characteristic of Mistol. Consisting of menthol, camphor, eucalyptol, and chlorbutol in a light oily solution that spreads promptly to all parts of the nasal mucosa, it relieves congestion, reduces discharge and clears the nasal passages within five minutes.

This symptomatic improvement also benefits the pathological state and tends to shorten the duration of the cold. Venous stasis in the mucous membrane is corrected, hyperemia diminished, and over-activity of the secreting glands checked. Repeated instillations of Mistol promote a more rapid return to normal conditions within the nares.

The formula of Mistol is the result of long and careful research, suggested primarily by prescriptions used for many years by leading rhinologists.

AETHER PURISS. B.D.H.

"I wish to say that I have used your Aether Puriss. under particularly difficult conditions. The patient was enormously fat and was anaesthetised for two and a half hours. For the most part of the time she was in the Trendelenburg position . . . she vomited once only and the induction was very smooth . . . there was no hypersecretion either in the nose or lungs. I think this is *very satisfactory.*"

The "*very satisfactory*" anaesthesia described above is directly attributable to the fact that Aether Puriss. B.D.H. is

"an absolutely pure product"

Sample for clinical trial on request

THE BRITISH DRUG HOUSES LTD. LONDON N-1

A.P.116

5% of pure iron (Fe) in readily assimilable form

. . . does not constipate, disturb digestion or discolour teeth

Colloidal Iron Concentrate	83%
Pure Alcohol	6%
Sugar	10%
Flavouring	1%

That is the formula of this tonic preparation, which contains a larger percentage of assimilable iron than has hitherto been provided in either a general or colloidal form. A more rapid response may therefore be anticipated from the administration of this preparation, which is very pleasant to take and well tolerated by all patients.
Idozan has no constipating effect, it does not derange the stomach or discolour the teeth. Though incompatible with alkaline salts, it may be combined with Liq. Arsenicalis and vegetable tinctures. It is therefore very suitable for therapeutic administration, where it is desired to give large doses of iron; both as a restorative after illness and in cases of anæmia it can be prescribed either with or without additional drugs with confidence and freedom.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates (both gold and vulcanite), Bridgework and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in any way injuring the softest gold or the finest vulcanite or platinum. The formula has been submitted to and approved by important members of the Medical Profession.

YOU'RE THE DOCTOR

A *Doctor* is one who teaches. A *Physician* is one who, by medical means, so assists the natural tendency towards *cure* that the human body displays in so many cases that ultimate recovery may be looked for. Where *cure* is impossible, as in Dental Caries, the only satisfactory course is *Prevention.*

And that is where Gibbs Dentifrice joins forces with every scientific and up-to-date Doctor and Dentist. It makes a valuable contribution to Preventive Dentistry. By powerful national advertising, and the constant reiteration of a few simple wholesome precepts, Gibbs urge upon the public the vital necessity for absolute cleanliness of the mouth, in preserving the teeth. And in Gibbs Dentifrice is provided the combination of ingredients that leading Medical Authority has prescribed as the most efficient for life-long use.

No extravagant claims are made for Gibbs Dentifrice. Never is it suggested that Gibbs Dentifrice obviates the need for professional advice. In fact, the most frequently recurring phrase in Gibbs Advertising is: "Visit your Dentist twice a year and use Gibbs Dentifrice twice a day."

Gibbs Dentifrice

BRITISH MADE

"VARIBAN"

Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. Self-adhesive, readily conforming to the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the continuance of light duties. Ensures rapid healing.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

Local Anæsthesia in Surgical Practice

UTERINE PROLAPSE

THIRD DEGREE WITH LARGE VESICOCELE

Operation: Watkin's interposition; Perineorrhaphy.

Mrs. B. D. F., aged 53.

Anaesthesia: Classical infiltration block, using 45 c.c. of a 0.5 of 1 per cent. Novocain-Adrenaline solution in perineum. A circumferential block about the cervix was made, using 30 c.c. of the same solution. The round ligaments were blocked as soon as they appeared, 4 c.c. of Novocain-Adrenaline solution being used in each case. The classical Watkin's operation was performed. The perineum was then repaired by the split septum method. Anaesthesia was ideal. Patient's pulse was 80 at end of operation, and she had no post-operative nausea, vomiting, or gas pains, and made an uneventful recovery.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

Digestibility

*(1) The Fat Content

FACTS ABOUT
LACTOGEN

The ease with which maternal milk can be digested by the infant is partly due to the distribution of the fat as numerous small globules. With an equivalent quantity of fat the globules in cows' milk are many times larger and correspondingly fewer in number. Digestion is thus retarded, since the surface offered to digestive action is considerably diminished. The cream-enriched milk used in the preparation of Lactogen is subjected to a special emulsifying process before drying. This reduces the large fat globules to a state of fine division—increasing by a hundred times the initial surface area. Lactogen, furnishing a fat allowance corresponding to that of the natural diet, can therefore be digested just as easily—even by the most delicate infant.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

BETTER MILK FOR BABIES

THERE IS NO SUBSTITUTE FOR 'PETROLAGAR'

Brand Paraffin Emulsion

Years of research have produced this emulsion of paraffin and agar-agar which occupies a pre-eminent place in the treatment of constipation.

'Petrolagar' is manufactured by a new improved pharmaceutical process, by which specially designed equipment the paraffin is atomised by hydraulic pressure and is held in this minutely divided state by the emulsifying properties of agar-agar.

'Petrolagar' contains the large volume of 65% liquid petrolatum, and is deliciously flavoured and pleasant to take.

Prescribe 'Petrolagar' for constipation and allied intestinal disorders.

PETROLAGAR LABORATORIES LIMITED,
Braydon Road, London, N.16.

VACCINE TREATMENT
OF
GONORRHOEA

In the treatment of Gonorrhoea the use of Vaccines, in conjunction with the usual routine treatment, materially shortens the course of the disease and prevents complications.

DETOXICATED VACCINES are recommended for preference owing to the massive doses which may be administered with little or no reaction, at the same time achieving great immunity, but where price is a consideration "Ordinary" Vaccines are available at very low prices.

For all early cases of Gonorrhoea, also in cases of Gonococcal Arthritis, Orchitis, Iritis, etc., Gonococcal Vaccine "A" is indicated. This is a pure Gonococcal Vaccine prepared from many strains (Polyvalent).

In cases of more than three or four weeks duration Gonococcal Vaccine "B" is recommended. This Vaccine is composed of equal parts of the above Vaccine "A" and the organisms found as secondary invaders in chronic cases.

Practitioners desiring additional information regarding the above Vaccines and also the special Gonococcal Products for Diagnosis and Test of Cure are invited to write to:

THE VACCINE DEPARTMENT:

GENATOSAN LTD.

LOUGHBOROUGH, LEICESTERSHIRE.

Telephone: Loughborough 292 *Telegrams: "Genatosan, Loughborough."*

Milk Intolerance.

For many years Benger's Food, as is well known, has been used by practitioners throughout the world as a routine diet in all gastric cases, debility, and in cases of milk intolerance. The reason for this may be briefly stated:—

Benger's Food is a special wheaten flour preparation containing, in suitable amount, the two natural digestive principles — Amylopsin and Trypsin — in a latent state.

It is devised and expressly intended to be used in conjunction with fresh cows' milk, or diluted milk, if desired.

The two enzymes are in such condition as to exert their digestive powers under the condition which obtains during the preparation for use.

The Amylopsin acts on the carbohydrates (Starch) of the Food and gradually changes it into soluble sugars (Dextrins and Maltose mainly, with a little Dextrose) more or less according to the length of time allowed for digestion.

The Trypsin acts on the gluten of the flour and on the proteins (Casein, etc.) of the milk so that the curd which forms is softened, and as a result it separates in the stomach in fine readily-digestible flocculi instead of large, often indigestible curds. The extent of digestion can be varied; *it is important to note that complete pre-digestion can never take place.*

Benger's Food contains no preservatives. It is palatable and is free from rough irritant particles.

These considerations show that Benger's Food is not merely a mechanical milk modifier — it is a real modifier of a peculiar character.

THE "LANCET"
describes it as "Mr. Benger's admirable preparation."

A Physician's sample will be sent post free to any member of the Medical Profession making application to the Proprietors:—

(Aesculapius)

EPHREGEL

Nasal Jelly.

A combination of Ephedrine and Adrenalin with suitable analgesics and aromatics in a water-soluble base.

Both Ephedrine and Adrenaline act directly on the vasomotor system, and when applied to a mucous membrane cause a constriction of the capillary blood vessels, thereby blanching the area and consequently reducing the congestion.

In EPHREGEL NASAL JELLY the rapid onset of the adrenalin is usefully supplemented by the prolonged action of the ephedrine, which is further enhanced by the water-soluble base in which the medicaments are incorporated.

EPHREGEL NASAL JELLY is specially suitable for the reduction of congestion of the mucous membrane of the nose, especially in Hay Fever, Rhinitis, and acute colds. It is eminently suitable for the treatment of nasal congestion in children. By its use, breathing space is quickly and comfortably increased in the nasal passages.

Issued in collapsible tubes fitted with a nozzle.

Prepared at Evans' Biological Institute, Runcorn.

THE CHARACTERS OF THE EARLY TEUTONIC ALPHABET: RUNES INLAID UPON A SCRAMASAX FOUND IN THE THAMES

It is believed that runes were originated by the Goths at that period in their migrations when they were living on the northern shores of the Black Sea—from about A.D. 200. The earliest known inscription goes back to the fourth century A.D. In the Black Sea region the Goths were in contact with Greeks and Romans. It is clear that many of the Runic characters were based upon those of the Greek and Roman alphabets, the modifications having come about in the process of carving them on wood. The Runic alphabet here reproduced is inlaid in brass and silver wire upon a scramasax, or sword-knife, recovered from the river Thames. The word *Rune* originally meant "a mystery," "a secret thing." Runes disappeared from general use in England during the eighth century, being supplanted by the Gothic alphabet evolved by Ulfilas.

BRITISH MADE THROUGHOUT.

Remarks
ON
EMPYEMA THORACIS*

BY
H. MORRISTON DAVIES, M.D., M.CH.CANTAB.
F.R.C.S.ENG.
MEDICAL SUPERINTENDENT, VALE OF CLWYD SANATORIUM; CONSULTING SURGEON, UNIVERSITY COLLEGE HOSPITAL, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, AND KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION

Empyema is of particular interest because, after hundreds of years of relative staguation, progress has at last been made. It is to the work done by Evarts Graham and the other members of the Empyema Commission[1] that we are indebted for the realization of the mistakes of the past, and for the very definite knowledge which constitutes an enormous advance in science and forms the basis of our technique to-day. To Evarts Graham and his colleagues we owe a greatly reduced mortality—a death rate which has been brought down in cases of streptococcal empyema from about 25 per cent. to a little over 4 per cent., and also a large decrease in the number of cases of chronic empyema, which are a very serious trial to the surgeon, a bugbear to the general practitioner, and a curse to the unfortunate patient.

Before the war little attempt was made to distinguish between an empyema caused by a pneumococcus and one caused by a streptococcus. Cases with pus in the chest were grouped into those due to tubercle, which it was generally realized should not be opened, and those due to pneumonia, which must be opened and drained. Operative procedure entailed controversial points of minor importance only, such as rib resection as against intercostal drainage, and vertical incision as against oblique incision. If the patient lived, it was creditable; if he died, it was fate.

It was the appalling mortality in some of the American Army camps during the epidemic of 1917–18, which averaged over 30 per cent. and in some camps was as high as 70 per cent., that led to the setting up of the Empyema Commission at Camp Lee, Va. As a result of the very efficient work of this commission the pathology of the disease, the physiology of open pneumothorax, and, in consequence, the modern line of treatment, were established. The application of the cardinal principles was followed immediately by the reduction of the mortality to 4.3 per cent.

PHYSIOLOGY OF OPEN PNEUMOTHORAX

To appreciate the rationale of modern treatment it is necessary to understand the physiology of open pneumothorax. It is of the first importance to realize the fact that the mediastinum, which seems to be a stout median partition between the two lungs, is not a rigid structure in the healthy chest, and can be regarded as of no greater resistant value than a dividing veil.

Under normal conditions there is a negative pressure, at the height of expiration as well as during inspiration, in both pleural cavities. If an opening is made into one pleural cavity the alterations in pressure in that side are immediately reproduced to an almost similar extent in the opposite side. The negative pressure changes to a positive pressure, except only at the height of inspiration. This positive pressure on the surface of the lung prevents the suction of air down the trachea into the lungs. An attempt is made almost immediately to overcome this difficulty by an increase in the amplitude (not necessarily the rate) of the respirations. The success of this compensation depends on the capacity of the individual to make the exertion and on the size of the opening into the pleural cavity. Failure means death by asphyxia. At the best, if the opening into the pleural cavity is no bigger than that of the glottis, the intrapleural pressures will remain positive during expiration but become negative during inspiration; that is to say, there is compression of *both* lungs during expiration and incomplete expansion during inspiration.

A perfectly healthy individual can withstand for a short space of time a considerably larger opening, compensating for it by a big increase in amplitude of respiration. There are, however, other factors which come into action, greatly increasing the seriousness of the situation. With inspiration and expiration the mediastinum flaps to and fro, causing great cardiac embarrassment; there is stasis of the venous system owing to loss of aspiration by the heart of the venous blood; there is great loss of heat from the exposed pleural cavity, and there is the danger of suction of infection into the pleural cavity.

To pass for a moment from the healthy chest to an extreme case of chronic empyema, quite a different picture is presented. In such a case, not only the lung, but the mediastinum, is so bound down by adhesions that no admission of air by however big an opening can affect the tissues beyond the barrier of thickened pleura: the open pleura has all the characteristics of an extrathoracic cavity. The only considerations in connexion with the opening are sepsis and loss of heat.

NATURE OF THE INFECTION

Once these facts are understood it is possible to consider the problem of empyema. There are, however, certain other factors associated with the nature of the infection which have to be grasped. In all pneumonias there is a very great loss of functionable lung tissue owing partly to the pneumonic consolidation and partly to the effusion. This loss seriously reduces the vital capacity. Vital capacity can be defined as the maximum amount of air which can be expired after a maximum inspiration. A pneumococcal pneumonia differs essentially from a haemolytic streptococcal pneumonia in that the reduction of the vital capacity in the former is very much less than in the latter, as can be seen by the comparative absence of dyspnoea and cyanosis in the pneumococcal type and the seriousness of these symptoms in the streptococcal. In the pneumococcal cases the extent of lung area put out of action is usually localized. In the streptococcal pneumonias it is more widespread: the bronchioles and bronchi are involved, and there is extensive interstitial infiltration, blockage of alveoli, and atelectasis. If, therefore, an individual with healthy lungs and a good vital capacity experiences embarrassment by an opening into the pleural cavity, how much more serious an effect must such an opening have in the case of a patient suffering from pneumonia, and especially if that pneumonia is due to a streptococcal infection—always supposing that the mediastinum is equally mobile in both cases.

Now, there is also a big difference between a pneumococcal and a streptococcal empyema. An empyema due to the pneumococcus is a comparatively late manifestation in the course of the disease. It is therefore termed "meta-pneumonic," because it is rarely diagnosed until the pneumonia has passed the acute stage, when resolution is taking place; by this time the vital capacity is again increasing and the rate of metabolism is diminishing. Moreover, from the onset, the pus is rich in fibrin, forming a deposit on the pleura and fixing the lung and

* A British Medical Association Lecture delivered at Harrogate.

mediastinum. The dangers associated with making an opening into the pleural cavity are therefore *comparatively* small.

A haemolytic streptococcal empyema, on the other hand, is syn-pneumonic. So early does it start in the course of the illness that it is thought it might at times actually precede the interstitial broncho-pneumonic change in the lung. At first the effusion is a thin greenish-brown turbid fluid, and it is not till two or three weeks later that it becomes a frankly purulent effusion, and that efficient adhesions have formed to fix the lung and mediastinum. An opening made, therefore, in the earlier stages exposes the patient to all the dangers of an open pneumothorax, at a time when vital capacity, toxaemia, and increased metabolism make him least able to tolerate it. If, however, this intensely toxic fluid swarming with streptococci is left pent up in the chest, there is the probability that the patient will die from toxaemia, if he does not die first from anoxaemia and heart failure produced by the compression effects of the fluid.

TREATMENT BY ASPIRATION

In aspiration, and preferably in oxygen replacement of the effusion, we have a simple means of removing the fluid from the thorax and, temporarily at any rate, of diminishing the toxaemia and preventing the disasters of excessive compression of the lungs. This should therefore be the first line of treatment in any empyema. It relieves the symptoms and allows time for the investigation of the pus and the identification of the causative organism.

It is most important to recognize from the very beginning that repeated puncture of the chest wall may be necessary. For this reason every care must be taken at the first exploration to cause so little pain or distress that later interventions are tolerated with equanimity. The preliminary puncture serves two purposes: it confirms the presence of pus and it enables a specimen to be obtained for bacteriological examination. The site chosen is the sixth or seventh interspace in the axilla. With a 1 c.cm. syringe and a moderately long but fine hypodermic needle the skin at the selected site is anaesthetized with 1 per cent. novocain. Through the centre of this area, through the intercostal space and the parietal pleura, the needle is driven, the anaesthetic being expressed from the syringe in a steady stream so that the whole track is completely anaesthetized. It is generally quite easy to detect the change in resistance as the needle enters the pleural cavity. Before the needle is withdrawn an attempt is made to aspirate some of the effusion into the syringe; if successful, this sample is saved for bacteriological examination. It is quite possible that the pus may be too thick to enter the needle, in which case the needle is withdrawn and another with a larger bore is fitted to the syringe and pushed through the chest wall along the anaesthetized track. When pus has been found this needle is withdrawn, the centre of the anaesthetized skin is punctured with a fine double-edged tenotome, and a trocar and cannula connected with a Potain's aspirator* is slowly driven into the pleural cavity. A most necessary precaution to ensure the proper working of the apparatus is the production of a negative pressure in the bottle and the testing of the apparatus by aspirating some sterile water immediately before use.

By simple aspiration there is a limit to the amount of fluid that can be withdrawn. The amount varies according to the size of the effusion, the amount of displacement of the intrathoracic organs, the degree to which these are fixed by adhesions, and the expansile capacity of the affected lobe or lung. The onset of cough, of discomfort, or of pain in the chest is an indication that the limit of safe withdrawal of fluid has been reached. If it is exceeded, great distress can be caused to the patient, and there is even the danger of acute oedema of the lungs and death. The whole of a small effusion can be withdrawn without the appearance of symptoms, but if the effusion is large, symptoms may occur when not more than two-thirds has been aspirated; while if there is much thickening of the pleura, discomfort can be experienced when about a half only, or less, has been withdrawn.

It is possible to overcome this disadvantage by replacing the fluid, whenever symptoms of excessive intrapleural negative pressure appear, with air, or, better still, with oxygen. When a Potain's trocar and cannula is used for the aspiration, a fine pneumothorax needle connected with a pneumothorax apparatus is inserted into the pleural cavity through a higher interspace. Through this, air or oxygen can be run in as required. Unless the effusion is very thick I prefer aspirating and replacing through a single needle with a bore of 1 mm. and having two connexions, each controlled by a tap. One connexion is for the Potain's aspirator and the other for the pneumothorax apparatus. This saves the patient having two areas anaesthetized and two punctures. In an emergency, when the Potain's apparatus only is being used, if too high a negative pressure has been produced, the tap can be turned off and the Potain's tube disconnected from the needle. A pad of sterile wool is placed over the outer opening. The tap is then reopened, when, by reason of the intrapleural negative pressure, air will be drawn into the pleural cavity through the wool, which sterilizes it.

The application of this method of treatment has proved sufficient in itself to effect a cure in some cases of pneumococcal empyema.* "There is, moreover, the additional fact that experience has shown that a small proportion of these streptococcus cases will recover merely by aspiration. This number amounted to 13 per cent. of the cases observed by the Empyema Commission."[2] Graham, however, goes on to point out the danger of repeated aspirations owing to the risk of the needle penetrating the lung, when the pleural cavity becomes reduced in size, and causing a lung abscess. Empyema due to the staphylococcus is rare, but serious. It must be treated on the same principle as a streptococcal infection.

In the majority of cases further measures are needed, but an open pneumothorax must not be produced until frank pus is present: even then it is not advisable if there is a chance that the empyema can be cured by some other method which offers fewer possibilities of secondary infection—for example, by siphon or suction drainage through an air-tight opening.

SUCTION DRAINAGE

The principle of suction drainage is the introduction through an intercostal space of a catheter connected with a tube which opens about 10 cm. below the level of an antiseptic fluid in a Woulfe's bottle under the bed. By this means the intrathoracic fluid is carried off as formed, no air can enter the pleural cavity, and a constant intrapleural negative pressure is maintained.

The following is the ideal method of effecting air-tight drainage. The skin and underlying tissues of the seventh

* [illegible] can be used instead of a Potain, if preferred.

* Prior to the great war, following success in the treatment of effusions by replacement by oxygen (*Lancet*, 1912, ii, 1774), I tried this method in pneumococcal empyemata. The cases were then too few in number and the results too inconstant to justify more than a private hope.

intercostal space in the posterior axillary line are anaesthetized with novocain as previously described. Before the needle is withdrawn pus is sucked into the syringe to confirm its presence at this point. With a fine-bladed knife a skin incision is made sufficient only to admit a large trocar and cannula, which is driven through the chest wall. The trocar is withdrawn and a catheter, in size sufficient to fit tightly into the cannula (size of outside bore preferably not less than 8 mm.), stretched on a rigid stylet, is passed through the cannula so as to project fully two inches into the pleural cavity. It is advisable, before starting, to mark the catheter at two points—the one three inches from the distal opening, and the other the length of the cannula proximal to the first point. The cannula is now withdrawn and the catheter is left *in situ*, fitting tightly in the wound.

Some arrangement must be made for irrigating the pleural cavity. The ideal method is to insert a second fine tube through the intercostal space immediately above the drainage tube. A gauze pad is then placed round the tubes, and over this a sheet of rubber, which is firmly fixed in place by strapping. During the insertion each tube must be kept closed; the larger is not opened till it has been connected up with the Woulfe's bottle, and the smaller one till connected with the irrigation solution.

As an alternative to the second opening for irrigation, a Y connexion can be inserted in the length of rubber tubing passing from the catheter to the bottle. To the third limb of the Y a short length of tubing is attached. This is kept closed with a clip when not needed for irrigation. A second clip must also be fixed on the rubber tube between the bottle and the Y connexion, so that this can be closed when the irrigating fluid is being run into the pleural cavity.

It is possible to introduce a catheter through an air-tight opening simply with a narrow-bladed knife and a pair of sinus forceps. This should not be attempted except in emergency, as it is not easy, and there is considerable risk of injuring the intercostal vessels unless the knife is kept close along the upper edge of the lower rib of the interspace.

Irrigation is not so much indicated in the early acute phase of the empyema as at the later period, when a deposit of flakes of lymph and fibrin is occurring. Carrel-Dakin's solution is the best, as in addition to its antiseptic action it has a solvent effect on the fibrinous deposit. It soon loses its efficiency in contact with the albuminous content, and must therefore be constantly renewed.

The most recent method advocated is that known as "tidal drainage." For this the catheter is connected by a short length of tubing to a bottle half filled with Dakin's solution, the bottle being placed just below the level of the chest. With each inspiration the solution is drawn into the pleural cavity and expelled with expiration. The solution requires to be changed frequently.

There are two objections to air-tight suction drainage: the tissues gradually lose their close apposition to the tube which excludes the air, but by that time the more serious risks of an open pneumothorax have disappeared, owing to the formation of adhesions. The second objection is that restless or delirious patients, and especially children, may pull the catheter out of the wound at a time when it is still essential to exclude the possibility of exposing the pleural cavity to the air. In treating such patients aspiration is very much safer.

Operative Procedures

By the time the effusion has become really purulent, the pleural membranes are thickened and the lung and mediastinum are immobilized; then, for the first time, the question of open operation can be considered. This, however, does not arise in that small percentage of cases in which aspiration is succeeding in arresting the effusion and obliterating the pleural cavity, nor in the somewhat larger number in which success is attending air-tight drainage. There are many cases, however, which need further treatment, either because aspiration is not a sufficiently continuous method of drainage, or because the catheter in suction drainage is becoming continuously plugged by lymph. The first question to decide is whether open drainage shall be through an intercostal space or by rib resection. Each procedure has its own advantages and disadvantages. The disadvantages of rib resection are that it takes slightly longer and is somewhat more of a strain for a patient who is seriously debilitated. Either operation is done under a local anaesthetic; this means the anaesthetization of two intercostal spaces for the rib resection and of one only for the intercostal incision. After rib resection there is the danger of fragments of bone getting into the pleural cavity and of rib necrosis, causing delay in healing. To prevent the latter the cut ends of the ribs should be plugged with sterile wax before they are exposed to infection. Rib resection does, however, afford adequate drainage, and gives room not only for the drainage tube, but also for an accessory tube alongside for irrigation. Intercostal drainage may not be possible if the ribs are too close together. Occasionally, when the tube fits tightly in the space, necrosis of a rib from pressure of the tube may occur.

The tube must be inserted at such a level that it drains the lowest part of the empyema cavity. This varies according as to whether there is an empyema of the whole cavity or a local one. It is advisable to explore first with a syringe and medium-sized hypodermic needle, after anaesthetization of the track through two or more interspaces, so as to ensure correct location. When the whole pleural cavity is involved the best position is usually through the seventh intercostal space, or by resection of part of the eighth rib in the posterior axillary line. Normally the pleural cavity extends lower than this into the costo-phrenic sulcus, but when an empyema is drained, and even before, this sulcus becomes obliterated by the organization of lymph and cellular deposit, and by the adherence of the lateral part of the diaphragm to the chest wall. If then the costo-phrenic sulcus is traversed by the drainage tube, the subsequent closure of the tissues round the tube leads to inefficient drainage, sinus formation, and irritation of the diaphragm. Cough from such irritation of the diaphragm may also be caused by the pressure of too long a tube inserted at a higher level. The tube, therefore, must not be too long. A projection of two inches within the cavity is ample to prevent its slipping out, if adequately secured. The tube should be of a wide bore, from 1.5 to 2 cm. It is a wise policy to insert a second much finer tube or a No. 10 catheter alongside the tube for purposes of irrigation.

The oblique and vertical incisions through the skin and superficial tissues have their respective advantages and disadvantages. The oblique incision requires less extensive anaesthetization of the tissues. The great objection to it is that if the arm is raised during the operation, when brought back to the side, it will be found that the cutaneous and subcutaneous incision is considerably below the level of the intercostal opening and tends, therefore, to distort the tube. While such a valve-like effect may be advantageous when [illegible] air-tight drainage, it is quite otherwise for open [illegible]. As a general rule the vertical incision through the [illegible] and subcutaneous tissues with an oblique [illegible] the rib or through the intercostal space [illegible]

The value of Carrel-Dakin's solution for irrigation has already been referred to. One of the causes of chronic empyema is the organization of lymph so that it forms a sheath over the lung, preventing its re-expansion. Unless the visceral pleura is sufficiently supple reapposition with the parietal pleura cannot take place. If, on the other hand, the cause of incomplete expansion of the lung is due to fibrotic changes in the lung itself, approximation of the pleural membranes may still be possible owing to displacement of the mediastinum. Dakin's solution, by virtue of its solvent action, can often so free the pathological deposit from the pleura that the lung is again mobilized and capable of re-expansion. This action of Dakin's solution may liberate the plug closing a bronchial fistula, the existence of which was unknown. In such a case the use of the solution must be discontinued on account of the irritating cough it produces, and the risk of inspiration into the lung.

It is sometimes difficult to decide when to remove the drainage tube. A tube left in too long is apt to be responsible for a chronic sinus. This, unless of long standing, will clear up by the simple expedient of taking the tube out. A drainage tube is a source of irritation and therefore of reinfection, and must be removed as early as possible. The indication is the character of the discharge and the re-expansion of the lung as shown by x rays. If the lung is showing itself capable of expanding again, the tube should be omitted as soon as the discharge has ceased to be purulent, and is sterile.

It is essential from start to finish to treat the wound and empyema cavity with every aseptic precaution. A patient discharged from hospital while there is still a cavity or a sinus may, for the want of an additional week or two weeks' rigid supervision and care, be condemned to further operations, or to years of drainage, or even to a premature death from chronic sepsis or cerebral abscess.

DIET AND EXERCISES

The importance of nutrition was indicated by Bell of the Empyema Commission. He found that unless the diet contained a large amount of calories a day (from 3,300 to 3,500), an adverse nitrogen balance was produced, which meant a serious loss of weight. Graham recommends lactose, which is easily disguised by fruit juices, and also the subcutaneous administration of a 2 to 3 per cent. solution of glucose. Water should be given in considerable quantities during the febrile stage.

After the acute phase is over, breathing and blowing exercises should be started to increase the inflation and expansion of the lung so as to aid in the obliteration of the cavity.

CHRONIC EMPYEMA

The causes of chronicity can be divided into two groups—(*a*) cases in which chronic empyema could have been prevented, and (*b*) cases in which healing is very difficult owing to the primary cause or to unavoidable complication. The first group unfortunately is considerably the larger. It includes empyemata either not recognized or not treated until the pleura has become a rigid membrane by organization changes; those in which drainage has been inefficient owing to the opening being too high or too small; those in which reinfection has occurred; those in which irrigation with Dakin's solution has not been done and was necessary to remove the deposited lymph in order to prevent organization or to arrest persistent infection. Finally in this group of preventable cases are those in which the chronic cavity is maintained by the presence of a foreign body, such as a drainage tube, or fragments of rib, or on account of osteomyelitis of the divided rib.

The second group, in which the chronic empyema is due to unavoidable complications, includes those cases with bronchial fistula, with associated fibrosis of the lung, or in which the primary cause was tuberculosis or actinomycosis.

The first line of treatment is directed to rectify, when possible, the original fault. Efficient and dependent drainage must be instituted, preferably by enlarging and extending the original opening, if that is practicable; if not, by making a new opening. Foreign bodies should be looked for and removed. Frequent irrigation with Dakin's solution will help to sterilize the cavity and may even effect a decortication of the pleural surface, separating off the organized lymph. Dakin's solution should not be used, however, if the case is tuberculous, or, as has previously been stated, if there is a bronchial fistula.

It is only when these measures have been given a full trial that the major operative procedures are indicated. The object of these is to mobilize the chest wall by denuding it of the ribs over the affected area, and at the same time mobilizing the lung by decortication—that is, stripping the organized lymph off the lung and pleura. When dealing with a cavity of any size, mobilization of the chest wall alone or of the lung alone is rarely adequate. The operations must be performed in a series of stages, and it is most important that approximation should start at the apex and that apposition should be secured over the upper area before an attempt is made to obliterate the lower segment. In cases of very large empyemata it may be necessary to dissect away the whole of the parietal pleura, together with the periosteum of the ribs and the intercostal muscles.

Bronchial fistulae may clear up spontaneously after free drainage has been instituted. If not, the opening should be cauterized. To obliterate a large chronic fistula the bronchus must be freed, the end cauterized and closed by sutures, and the lung mobilized so as to bring it into apposition with the chest wall.

THE EFFICIENCY OF ANTISEPTICS USED IN MIDWIFERY

BY

LAWRENCE P. GARROD, M.B., M.R.C.P.

LECTURER IN BACTERIOLOGY, ST. BARTHOLOMEW'S HOSPITAL

Early last year it was pointed out in the correspondence columns of the *British Medical Journal*[1] that doubts had been raised of the utility of lysol as an antiseptic for obstetric use. A memorandum circulated by the London County Council, and reissued by the Central Midwives Board, gave particulars of tests which indicated that only comparatively strong solutions of lysol were capable of killing *Streptococcus pyogenes*, and, further, that different brands of lysol varied considerably in their bactericidal potency. It was not unnaturally asked what antiseptic should be substituted for lysol in midwifery, and this question has not until now, so far as I am aware, received an answer, either in the medical press or in the pronouncement of any public health authority. Meanwhile the Central Midwives Board has recommended the continued use of lysol by midwives, provided that it conforms to a certain chemical standard—namely, a 50 per cent. cresol content.

To those familiar with the properties of germicides the use of lysol in obstetrics has always appeared mistaken. It is the most caustic of all antiseptics in clinical use, with the single exception of phenol, and the limitations imposed by this property on the strengths of solutions employable bring them dangerously near a point at which they are ineffective. There is therefore a prima facie case for inquiry into the suitability of other agents, but it may first be asked whether the use of a germicide as such—that is, with an expectation of destroying bacteria—is desirable or useful in midwifery. The ideal of some obstetricians is "asepsis," and they do not apparently believe in the utility of any attempt to destroy bacteria by chemical means; if they use lysol it is for other reasons (though it is to be noted that the vast majority of practitioners regard lysol in the light of a safeguard against infection). Some colour has been lent to this view by the work of Colebrook,[2] who found that none of a number of germicides was capable of sterilizing the skin of hands artificially infected with streptococci.

Assuming that puerperal infection is exogenous, the question at issue is whether treatment of the vulva and vagina with an efficient germicide will or will not destroy streptococci which may gain entry to the birth canal during childbirth. Making every allowance for the difference between conditions *in vitro* and *in vivo*, there is strong presumptive evidence that such an action can be exerted. If chemical prophylaxis is a myth, why do obstetricians themselves instil silver nitrate solution into the conjunctiva to prevent ophthalmia neonatorum? To take an example from the vagina itself, has anyone ever disputed the efficacy of the mercury and silver preparations issued to troops during the war for the prophylaxis of syphilis and gonorrhoea? And, as a third example, who has ever heard of a surgeon during the last forty years opening an abdomen without first attempting to sterilize the skin, again by chemical means? It is a common-sense view that prophylaxis is the really useful sphere of germicides. Their utility in established infections is more doubtful, although they are employed for treating septic wounds, and are even injected into the blood stream in septicaemia; but to kill a streptococcus before it has gained access to the tissues, to erect a barrier through which it cannot pass alive, is surely not an impossible thing. If a germicide cannot do this it can do nothing.

The success of measures hitherto adopted for reducing the persistently high mortality from puerperal sepsis has not been such as to permit the neglect of any measure reasonably calculated to assist in attaining this object. It is therefore submitted that an antiseptic technique aimed at prophylaxis is worthy of extensive trial, and the experiments to be described were designed to determine what agent is likely to be most efficient for this purpose. It is a common practice to decry *in vitro* tests of germicides as unreliable indicators of activity *in vivo*, and however laboratory conditions may be modified to imitate clinical conditions, no one would care to rely for clinical purposes on the maximum dilution found to be effective in the laboratory. Often, however, it is possible to use for clinical purposes considerably stronger solutions, and in any case the same consideration applies to all the agents tested: the most active under appropriate conditions *in vitro* may reasonably be assumed to be the most active *in vivo*.

It is not sufficiently well known that the action of any germicide may differ widely with different bacteria. The statement of a Rideal-Walker coefficient, the only evidence (if any) usually adduced of the activity of a germicide, refers to its action on *B. typhosus*; for a streptococcus its lethal activity may be greater or less to a considerable degree. It is therefore important, when considering germicides in relation to any given lesion, to possess comparable data concerning their action on the micro-organism causing that lesion. A strict comparison is only possible if all have been tested under the same conditions. The organism used in the present investigation was *Strep. pyogenes*, which is unquestionably responsible for almost all fatal and the majority of other grave cases of puerperal infection.

METHOD OF TESTING

Each germicide was tested in four ways. The bactericidal action (that is, the ability to destroy the streptococcus in a given time) was studied under two conditions: in a medium of distilled water with no added organic matter, and in the presence of a proportion of added blood at the temperature of the body. The bacteriostatic action (that is, the ability to prevent growth without necessarily destroying) was studied also under two conditions—namely, in media containing no protein, and in media containing blood. The use of blood as added organic matter appears justified by the conditions in which a germicide is used in obstetrics; the material with which it will chiefly be mixed when its presence is designed to prevent the access of bacteria to the placental site or a cervical laceration, is blood. Serum, which has often been used, appears less appropriate to the purpose here in view, and such materials as milk, urine, sterilized faeces, etc., are clearly less applicable.

The following are details of the technique employed:

A single strain of *Strep. pyogenes* was used throughout; its origin, which was recent, was blood culture from a rapidly fatal case of septicaemia following abortion. The preparation used for tests was not the usual broth culture, but a suspension of a strength of at least 1,000 million per c.cm. prepared by emulsifying a twenty-four-hour blood-agar plate in saline, and treatment in a mechanical shaker. Broth was avoided in order to exclude extraneous organic matter completely, and the object of shaking was to break down clumps of cocci, the presence of which, owing to failure of penetration by the germicide, may undoubtedly vitiate results with this organism. For the purpose of tests in the first category, two drops as delivered by a small separating funnel (equivalent to slightly less than 0.1 c.cm.) of this emulsion were added at timed intervals to a range of tubes containing approximately 4 c.cm. each of a range of dilutions of the germicide; these were shaken and left at room temperature; cultures were made after fifteen minutes, a 2 mm. loopful being sown in blood broth. The presence or absence of growth in the cultures was noted after forty-eight hours.

The dilutions used rose by 50's from 100 to 500, by 100's to 1,000, by 200's to 2,000, by 500's to 5,000, by 1,000's to 10,000, and thence as multiples of the foregoing.

In the tests of bactericidal action at 37° C. in the presence of blood, the dilutions of the germicide were reduced to a volume of 4.5 c.cm. in tubes graduated for this purpose, which were placed in racks in a water-bath at 37°. After the contents of the tubes had reached that temperature each received 0.5 c.cm. of a mixture of equal volumes of sterile defibrinated blood and saline emulsion of streptococci (in one series of experiments citrated blood was used). Each tube thus contained an amount of blood equivalent to 5 per cent. of the total volume of fluid. The tubes were shaken, kept in the bath for fifteen minutes, and then cultivated in the same manner as the others. It was originally intended to prepare dilutions of such strength that the addition of 0.5 c.cm. would bring them to the dilutions used in the foregoing series of experiments. It was found more convenient, however, to use the same actual solutions for both, and the dilutions in this series have therefore to be corrected for the addition.

For the tests of bacteriostatic action 500 c.cm. double strength peptone broth was made up to 800 c.cm. and tubed in 4 c.cm. amounts; to each was added 1 c.cm. of a dilution of the germicide, the dilution in the resulting mixture with the medium being thus five times greater, and the concentration of the other ingredients correct. These tubes, with or without added blood, were inoculated and read after forty-eight hours. Owing to difficulty in observing whether growth had occurred

in some of the cultures containing blood, several of these experiments were done using tubes of 4 c.cm. agar, which were sloped and surface-sown. Parallel experiments using both media showed that the results given by the two were identical.

Many of the experiments were done several times, either because a wrong range of dilutions had originally been used, to confirm unexpected results, or to reconcile conflicting results. Some of the figures given represent averages of the results of several experiments; it is admittedly impossible to attain perfect consistency in repeated experiments of this kind.

A word of explanation is necessary for the procedure of cultivation, after exposure to the action of the germicide, in *blood* broth. It had been observed by the writer some years ago that the use of this medium rather than plain broth reduced the apparent efficiency of a germicide for streptococci as much as twenty-five-fold. It appeared that exposure to weak solutions reduced their vitality, with the result that they failed to grow in a poor medium, but grew readily if it were enriched by blood. This observation was fully confirmed in this series of experiments. In some of them, cultures after the fifteen minutes' exposure were made in both media with greatly contrasted results. Thus the apparent maximum effective dilutions, as indicated by subsequent growth in the two media, were as follows:

	Broth.	Blood Broth.
*Mercury perchloride...	1: 10,000	1: 250
Brilliant green ...	1: 25,000	1: 4,000
Acriflavine	1: 2,500	1: 900

That this phenomenon is not peculiar to streptococci is shown by the fact that similar results were obtained with mercury perchloride and *B. coli*. Other experiments indicate that the cells rather than the plasma contain what may be called the growth-stimulating factor. The nature of this phenomenon is being made the subject of a separate investigation. All the figures given in the tables represent the results of cultivating in blood broth, which, as will have been seen, is the severer test of bactericidal action.

DISCUSSION OF RESULTS

Table I gives the whole of the results in figures;

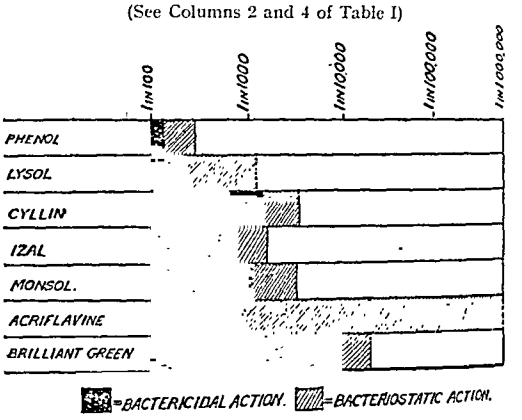
TABLE I.

	1	2	3	4
	Maximum	Maximum	Maximum Dilution in culture inhibiting growth in peptone broth	Maximum Dilution in culture inhibiting growth in peptone broth + blood
	water at room temperature	presence of 5 per cent. of blood*		
	1 in	1 in	1 in	1 in
Phenol	100	150	400	500
Eusol	500	2	5	<5
Mercury biniodide	50	100		
Mercury perchloride	250	400	50,000	12,500
Lysol 1	650	300	4,000	1,500
„ 2	450	300	2,000	1,000
„ 3	1,600	500	6,000	2,000
„ 4	600	300	6,000	1,000
Cyllin (medical) ...	2,000	1,800	5,000	5,000
Izal	3,000	800	5,000	2,000
Monsol	700	1,200	10,000	5,000
Acriflavine	900	500	1,250,000	1,250,000
Hexanol	400	600	200,000	200,000
Brilliant green ...	4,000	10,000	1,250,000	30,000
Mercurochrome	<100	<100	12,500	500

*Figures in this column, for strict accuracy, require a correction of + 11 per cent. for the volume of blood and bacterial suspension added.

Table II represents the more important of them diagrammatically. The scale of this diagram is logarithmic, with the dilution 1 in 100 as zero; the maximum bactericidal and bacteriostatic dilutions are represented in the case of each germicide, the figures used being those in the second and fourth columns of the table. Emphasis is thus laid

TABLE II.—*Comparative Efficiencies of Seven Germicides Tested*
(See Columns 2 and 4 of Table I)



on bactericidal action at 37° in the presence of blood and on bacteriostasis in blood-containing media, because it is believed that these conditions more truly represent those which obtain in clinical use. It is noteworthy that two factors are concerned in the former, which account for differences between the results and those of ordinary tests at room temperature without organic matter (Column 1 of Table I): the higher temperature, which usually intensifies bactericidal action; and the presence of blood, which often diminishes it. The varying effects of these two factors combined are interesting.

Some of the results call for brief individual comments.

Eusol.—The contrast between the effective bactericidal strength of eusol in distilled water and its behaviour in the presence of blood, or even peptone broth, is striking and familiar. It cannot be emphasized too strongly that agents of this class are worthless in the presence of any considerable amount of organic matter.

Mercury Salts.—The effect on the results obtained with these agents of cultivating in blood broth has already been discussed: this method shows that mercury salts have considerably less bactericidal power than is usually supposed. Somewhat surprisingly, they are effective in greater dilution at 37° C. in the presence of 5 per cent of blood than in distilled water at room temperature. Of the two, the biniodide is much the weaker, but according to these results neither can be effective in the dilutions used clinically.

Lysols.—Lysol 1 is the original German lysol (Schulke and Mayr); the other three are well-known brands sold in England, all having a guaranteed 50 per cent. cresol content. Their bactericidal power varies: one is somewhat inferior to its foreign prototype, one decidedly superior, and one identical. Excluding from consideration No. 3, which clearly must contain different cresols from the remainder, the maximum effective bactericidal concentration under clinical conditions is 1 in 300. The strength of No. 2 recommended for use in the vagina is 1 in 400. This lysol therefore fails. It is equally clear that the use of any lysol, even in somewhat stronger solution, can leave very little margin of safety.

Cyllin, Izal, and Monsol.—These are proprietary germicides of coal-tar origin, all of which form an emulsion, as distinct from a solution, when diluted in water. Their average efficiency is much greater than that of lysol. A comparison between their action in distilled water and in 5 per cent. blood at 37° C. is interesting: cyllin appears almost equally effective in

either condition; izal is better under the former, and monsol under the latter. These germicides are less poisonous than lysol and less irritating to the skin, despite their much greater efficiency. They can, however, presumably be irritating in the vagina, since the strengths recommended for use are respectively 1 in 600, 1 in 600, and 1 in 500 (increased). Even in these weak dilutions there is a clear margin of safety.

Acriflavine and Rivanol.—These may be considered together, since they are compounds of somewhat similar composition, and they share the property of exerting a bacteriostatic action in enormous dilutions, whereas their bactericidal power in short periods of time is comparatively feeble. The former action is in both cases unaffected by blood. The bactericidal power of acriflavine is somewhat diminished by the presence of blood: this contrasts with the statement that it is actually enhanced by the presence of serum (Browning).[3]

Brilliant Green.—It may be said at once that brilliant green emerges from this investigation as by far the most potent of all the substances tested. The fact that it destroys *Strep. pyogenes* even in the presence of blood at a dilution of 1 in 10,000 becomes even more striking and significant when it is remembered that even strong solutions are without irritant action. In "blue paint" (Bonney and Browning)[4], which has now been used for obstetric and other purposes for fifteen years, its concentration is 1 in 200. It is thus practicable to employ a solution of fifty times the strength demanded for rapid bactericidal action.

Mercurochrome.—It is evident from the results in Table I that mercurochrome (of which two makes were tested) is a germicide incomparably weaker than is commonly supposed. Others have obtained similarly unsatisfactory results with it (Simmons,[5] Ramos,[6] Walker[7]), and an explanation of the discrepancy between these results and those of Young, who introduced the drug, has been suggested elsewhere (Garrod).[8] A solution of a strength of no less than 1 in 25 has, however, been said to reduce the incidence of puerperal sepsis (Mayes).[9]

COMMENTARY

In drawing practical conclusions from these results it is necessary first to decide whether the purposes of obstetric prophylaxis can be served by merely bacteriostatic action; if this be so, acriflavine is the most powerful agent we possess. In order that this action should be effective, an adequate concentration would presumably have to be maintained in the birth canal for several days, immobilizing any streptococci which might gain entrance, until the states of the placental site and the cervical laceration were such that bacterial invasion could no longer readily take place. That a rapid bactericidal action, if obtainable, is preferable to this, must be obvious.

Of the germicides tested, few possess a bactericidal action on *Strep. pyogenes* which appears adequate. The meaning of the chief results may be concisely stated by calculating the ratio of effective strength to strength employed, which may be termed the factor of safety. Taking the figures in Column 2 as the effective bactericidal strength, the factor of safety for brilliant green is 50, for cyllin 3, for lysol 0.75, for mercury biniodide 0.1. The contrast thus afforded between two effective and two ineffective agents is sufficiently striking.

There is no doubt that brilliant green is by far the surest safeguard against streptococcal infection which can be used; it would be interesting to know whether grave sepsis has ever been seen to follow its employment. It is objected to on account of its staining propensities; whether stained linen or death from septicaemia is the greater evil is a question which seems to admit of only one answer. Next in order of efficiency come the proprietary coal-tar germicides, monsol, izal, and cyllin; these are sometimes objected to on account of their smell. Acriflavine, rivanol, and one brand of lysol are on the borderline of bactericidal efficiency; other lysols, mercurochrome, and mercury salts are ineffective.

The purpose of this paper is to indicate which germicides may be expected to prevent streptococcal infection during childbirth: the method of their application is outside its scope. That a technique can be devised which would ensure their effective action is hardly doubtful.

CONCLUSIONS

1. The bactericidal and bacteriostatic action of fifteen germicides used in obstetrics have been tested, the test organism being *Strep. pyogenes*, and the conditions employed such as to imitate as far as possible those of obstetric use.

2. Four of the germicides tested are calculated to be effective in the dilutions employed clinically, one, brilliant green, affording a very wide margin of safety; of three the efficiency is doubtful; the remaining eight are judged to be untrustworthy.

This work was carried out during the tenure of a grant for work on streptococci from the Medical Research Council, to whom I express my thanks, and to my assistant, Miss G. E. Root, for assiduous help in the laborious work involved.

THALLIUM ACETATE IN TREATMENT OF RINGWORM OF THE SCALP

A STATISTICAL INVESTIGATION OF SUBSEQUENT NUTRITION

BY

G. H. PERCIVAL, M.R.C.P., PH.D.*

(From the Pharmacological Laboratory, University of Edinburgh, and the Skin Department, Royal Infirmary, Edinburgh)

Since November, 1928, 139 children suffering from ringworm of the scalp have received an epilating dose of thallium acetate at the skin department, Royal Infirmary, Edinburgh. The dosage employed was 8.5 milligrams of thallium acetate per kilogram of body weight; this was administered to children weighing up to 33 kilos. The treatment has been successfully completed in 122 of these cases, the remaining 17 being still under supervision. During the same period only 29 children suffering from ringworm of the scalp have received an epilating dose of *x* rays. From a survey of the cases treated with thallium acetate it seems that the immediate results of this method of treatment are on the whole superior to those obtained in cases treated by *x* rays.

ADVANTAGES AND DISADVANTAGES OF THALLIUM

Thallium is easily and rapidly administered. On account of this a large number of children can be dealt with in a very short time, whereas an epilating dose of *x* rays for the entire scalp takes at least an hour to administer.

* In receipt of a grant from the Medical Research Council.

even with appropriate apparatus and skilled technique. This fact renders thallium especially suitable when a sudden epidemic has to be dealt with. For instance, a comparison of the average period elapsing between the administration of thallium and the treatment by *x* rays respectively and the discharge of the case, shows that in 122 thallium cases this period was 113.5 days; in 29 *x*-ray cases of one series it was 152 days, and in 50 cases of another group it was 135 days. Further, in 1923, the average period of isolation of ringworm cases treated with *x* rays was seven months, this delay being due to the occurrence within a short period of time of a large number of cases which could only be dealt with gradually on account of the time occupied by the administration of the *x*-ray dosage. Epilation with thallium is as certain as that obtained by *x* rays; there is no risk of permanent baldness, and it can be produced in children who are too young to receive *x*-ray treatment.

On the other hand, the alopecia resulting from thallium is of much shorter duration than that brought about by *x* rays, so that with thallium very careful local antiparasitic treatment is required. Another disadvantage of thallium is that it regularly produces mild constitutional symptoms in a proportion of cases (44 per cent. in 50 of the present series). These are never serious with ordinary dosage (up to 0.25 to 0.28 gram) in children under 11, and are no more severe than those which may accompany scarlatinal or diphtheria immunization. They are quickly recovered from, and no immediate harm seems to result. In view of the fact that they do occur, that thallium is a substance capable of producing, in larger doses, profound toxaemia and grave pathological changes, and that its fate in the body and mode of action as a depilatory substance are unknown, it is possible that it may cause deleterious influences on growth and development which only become evident at some later period. Up to the present, however, no data on this subject have been available. This aspect of the problem is obviously a most important one if the therapeutic use of the drug is to be continued.

STATISTICS OF TREATMENT

Through the courtesy, and co-operation of Dr. Guy, medical officer of health for Edinburgh, I have been able to follow up a series of 76 male and female school children who received thallium acetate treatment for ringworm of the scalp at periods varying from four months to two years. Each of these children was examined physically, and all appeared to be healthy; indeed, many of the parents volunteered the statement that in their opinion the child's general health had improved after the administration of the thallium. In addition, each child was measured and weighed. The group consisted of 51 males and 25 females.

First of all the children were divided into age groups according to their age on the last birthday, and the average weights of the corresponding age groups before and after thallium administration were compared. The average weights on these two dates do not represent the weights of the same children for any one age group, since a child aged 5 at the time of administration of thallium may have been examined eight months or two years later, in which case this child's weight would go to make up the average either of age period 5 again, or of age period 7. In spite of this, the data provide a comparative index of the nutrition of the children before and after thallium administration, since the weights before thallium treatment indicate the type of population dealt with and those after thallium deal with the same population, so that any redistribution into different age groups is immaterial. The average weights on these two dates were compared with the average normal weight of Edinburgh school children for the same age periods. The total numbers in each age group were as follows:

TABLE I

Age Last Birthday	Males		Females	
	Before Thallium	4 months to 2 years after Thallium	Before Thallium	1 to 2 years after Thallium
1	1	—	—	—
2	—	—	—	—
3	1	1	1	—
4	5	1	3	—
5	10	3	1	2
6	10	9	6	3
7	11	10	7	4
8	8	10	3	6
9	4	9	2	5
10	1	5	1	3
11	—	3	1	1
12	—	—	—	1
	51	51	25	25

Table II shows the average weights in kilograms according to age period of 51 male children immediately before the administration of thallium, and of the same children four months to two years after they had received a single epilating dose of thallium. The average height in inches and the average normal height is also shown.

TABLE II.—*Males, Four Months to Two Years after Thallium*

Age Last Birthday	Average Weight before Thallium	Average Weight 4 months to 2 years after Thallium	Average Normal Weight	Average Height 4 months to 2 years after Thallium	Average Normal Height
1	11	—	9.5	—	
3	13.9	16.6	14.1	38 1	
4	15.74	15.9	15.9	35.5	
5	18.32	17.53	18.2	41.4	
6	19.32	20 6	20.2	44.3	
7	22.22	22.8	22.6	46.4	4
8	23.59	25.4	24.9	49 3	47
9	24.2	27.9	27.4	49.57	49
10	25 4	25.6	30 7	49 6	51.
11	—	28.3	32.7	51.3	53

TABLE III.—*Females, One to Two Years after Thallium*

Age Last Birthday	Average Weight before Thallium	Average Weight 1 to 2 years after Thallium	Average Normal Weight	Height 1 to 2 years after Thallium	Average Normal Height
3	14.4	—	12.6	—	—
4	15.8	—	15.4	—	—
5	17 9	17.9	17.8	40	40.5
6	19 1	20.0	18.9	45 5	42 8
7	20 88	23.0	21.3	45	44.5
8	23.4	23.9	23.7	47.4	46.8
9	25.5	26.2	25.2	48.4	48.7
10	26.06	28.5	28.1	52.9	51
11	28.24	31.8	33.9	51	53 1
12	—	32.7	34.7	55.5	55 6

In order to control the results of a comparison of the average weights before and after thallium, and of the average normal weight classified according to age periods, the average weights after thallium according to height were compared with the average normal weights for the same heights. Table IV shows the average weight in kilograms according to height in inches four months to two years after thallium in 51 male children, and one to two years after thallium in 25 female children.

TABLE IV.—*Males and Females*

Height in Inches	Males		Females	
	Average Weight 4 months to 2 years after Thallium	Average Normal Weight	Weight 1 to 2 years after Thallium	Average Normal Weight
35	15.9	14.1	—	—
38	15.6	15.9	—	—
40	19.1	17.4	16.3	16.8
41	16.8	18.2	21.3	20.58
43	19.8	19.4	22.2	21.8
44	20.3	20.2	22.6	22.4
45	21.2	21.3	24.8	23.9
46	21.9	22.6	27.2	25.59
47	23.8	24.9	30.7	28.1
48	24.6	25.8	30.4	29.5
49	24.4	26.7	29.0	30.9
50	26.9	28.1	32.7	34.5
51	28.1	29.5	—	—
53	28.6	32.7	—	—
55	34	35	—	—

An analysis of Tables II and III shows, first, that immediately before the administration of thallium the average weight according to age of the 51 male and 25 female children dealt with in the investigation compares favourably with the average normal weight for the corresponding age periods. The weight of the males up to the age of 7, and of the females up to the age of 9, is practically identical with the average normal weight, but in the later age periods it is anything from 1.4 to 5 kilograms below normal. The difference is greatest in the males. It is to be noted, however, that in both cases there were fewer children in the age periods 9 and 10 years than in the age periods 4 years to 8 years. In Table II the average weight of the same children four months to two years after thallium is seen to be on the whole better than that for the corresponding age periods immediately prior to the administration. Table I shows that this improvement cannot be due entirely to a redistribution of the children into different age periods, at least for the period six years to eight years, since almost the same number of children appear in these groups before and after the administration of thallium. In Table II there is a fall in weight below the average normal weight for the age periods 9, 10, and 11 years, and this corresponds to that found in the average weight, before thallium was given, for the periods 8, 9, and 10 years. The average weights of the female children one to two years after thallium administration is quite appreciably higher than the corresponding average normal weights.

Table IV shows that in both male and female cases the height four months to two years, and one to two years after thallium administration bears a normal relationship to the weight; and Tables II and III show that the average height at a similar period after thallium administration is normal for the various age periods. In males the height for the age periods 10 years and 11 years is below the average normal, but this corresponds to the subnormal average weight for the same periods. As the period elapsing between the first and second weighings varied in most of the children, no attempt has been made to ascertain the average increase in weight during this interval of children of corresponding age periods or heights.

CONCLUSION

Examined from several aspects the weights and heights of both male and female children four months to two years after thallium administration do not appear to show any gross deviation from the normal. In fact, below 10 years of age the figures are, if anything, slightly better than normal. Using the weights and heights observed in this investigation as standards on which to interpret physical development, and taking into account the results of a general medical examination, there is no evidence to show that the continued normal growth and nutrition of children are adversely influenced or interfered with as a result of the previous administration of thallium acetate in sufficient quantity to produce epilation of the scalp.

PERITONITIS DUE TO PERFORATION OF THE BOWEL BY FOREIGN BODIES

BY

ARTHUR HAWKYARD, M.D.

LORD MAYOR OF LEEDS

AND

GEORGE ARMITAGE, *M.C.*, CH.M., F.R.C.S.

LEEDS

The following report (communicated to a recent meeting of the Leeds and West Riding Medico-Chirurgical Society) of the personal experiences with a fish bone which had been swallowed by one of us (A. H.) may be of general interest.

During October, 1929, I began to suffer from pain between the shoulder blades, which seemed to originate in the stomach. There was no pain over the stomach in front. The pain commenced as a feeling of discomfort, gradually developing a very definite character, varying greatly in intensity and in duration. When the pain was at its worst it gave rise to a feeling as if the chest would burst open. I thought at first it was angina, but soon decided that it was not so. Then I thought it was duodenal in position, and naturally wondered if an ulcer was the cause. I found out that the attacks came on mostly in the afternoon, when the stomach was empty. The pain could be cured by taking a drink of some kind or a biscuit. As I have not eaten lunch for forty years my stomach is always empty in the afternoon. The attacks of pain gradually got more severe, and the last attack I suffered from was on July 22nd, 1930. For a month prior to this date I had been in bed suffering from the effects of a motor accident. This period of rest did not alter the attacks of pain in any way. On July 24th I voided, per anum, a fish bone (Fig. 1). I have never had an attack of pain since.

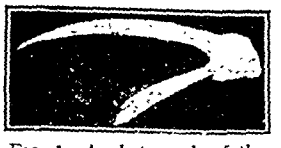

FIG. 1.—A photograph of the fish bone swallowed.

Dr. Walter Garstang, professor of zoology in the University of Leeds, informs me that the bone is the

post-temporal bone of the whiting (Fig. 2). It is one of a string of bones attaching the pectoral girdle to the back of the skull. From the shape of the bone one can see that the pain was caused by the bone presenting at the pyloric orifice with the two prongs in front, so that it was impossible for it to pass in this way. Taking something into the stomach evidently had the effect of dislodging it for the time being. The bone presented a

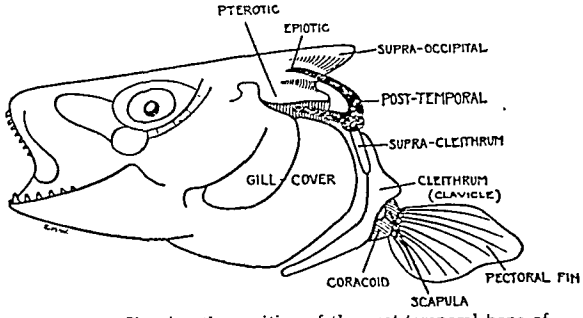

FIG. 2.—Showing the position of the post-temporal bone of the whiting.

dark appearance, no sign of digestion being apparent. I suffer from pernicious anaemia and have achlorhydria, which may account for the bone not having been digested.

The case is interesting because of the length of time the bone was retained in the stomach. It seems a wonder the bone did not perforate the stomach wall, and it was only a fortunate chance which allowed the bone to pass the pylorus.

It may be that many of the cases of atypical duodenal ulcer one sees are due to bones and other objects being in the stomach. A few years ago I removed from a man's rectum a piece of twig three inches long and three-sixteenths thick, which had been embedded there for four years. In this case the man had suffered from indigestion for a long time before the pain was transferred to the rectum.

Commenting on this case the other author (G. A.) referred to the case of triple perforation of the ileum by fish bones (brill) reported in the *British Medical Journal* (1928, i, 307), and suggested that it was advisable to be always on the look out for foreign bodies perforating the bowel wall as a possible cause of an unexplained peritonitis, labelled idiopathic or haematogenous, somewhat unsatisfactorily in many cases.

Three days later the following case was referred to hospital by Dr. Sinton of Headingley.

W. L., aged 62, a clothworker, was admitted to hospital on January 12th complaining of severe generalized abdominal pain. This pain commenced very suddenly, and without warning, twenty hours previously, across the lower abdomen, giving rise to a strong desire to defaecate. It was of a colicky type, with only occasional brief intervals of relief, bringing him almost double to the floor, and making rest quite impossible. Nausea was present from the beginning, but vomiting did not occur until nine hours later. All symptoms increased in severity, compelling him to call in Dr. Sinton, who dispatched him to hospital immediately. On admission the patient looked ill and was cyanosed. Pulse rate was 120, temperature 97° F., blood pressure 140/80, respirations 20. The tongue was dry, dirty, and coated. Examination revealed a hard, rigid abdomen, which could not be overcome, and which was extremely tender. There was slight pain on flexion of the right leg. Rectal examination revealed high anterior tenderness, but was otherwise negative. A diagnosis of general peritonitis was made with no little assurance, but the cause remained obscure. The patient volunteered no information when he was asked if he had swallowed a foreign body. Operation was carried out immediately under spinal novocain anaesthesia (150 mg. in 15 c.cm. cerebro-spinal fluid; level 1-2 dorsal) after preliminary medication consisting of hypodermic injections of morphine 1/4 grain, atropine 1/100 grain, and adrenaline (1 in 1,000) 15 minims. Free sero-purulent effusion was present in the general peritoneal cavity, especially in the lower part. A normal appendix was removed. Having in mind, in view of the recent discussion, the possibility of a foreign body, a perforated diverticulum, or a stercoral ulcer of the large bowel proximal to a growth, the surgeon on searching the pelvis felt a sharp foreign body projecting from the anterior aspect of the lower sigmoid colon. This proved to be the sharp end of a rabbit's rib, which when removed measured 2 inches (Fig. 3). This bone was shown to the patient at the time of removal, and he at once remembered having partaken somewhat vigorously of a hearty dish composed of rabbit, onions, and potatoes two and a half days prior to the onset of the pain. The perforation was sutured, infolded, and an omental graft placed over it. The peritoneal cavity was drained. Convalescence proceeded uneventfully, and the patient was discharged from hospital cured four weeks later.

FIG. 3.—Showing the rib bone of a rabbit, which had perforated the lower sigmoid colon, giving rise to general peritonitis. (Natural size.)

The case is placed on record because it is felt that, occasionally, foreign bodies perforating the bowel and producing general peritonitis are missed. It is advisable in these obscure cases to inquire very carefully into the nature of meals partaken prior to the onset of the malady.

We are indebted to Mr C. Gillinson, under whose care the patient was admitted, for permission to report the case, and to Miss E. M. Wright for Figure 2.

THE GONOCOCCAL COMPLEMENT-FIXATION TEST

BY

I. N. ORPWOOD PRICE, M.R.C.S., L.R.C.P., D.P.H.

PATHOLOGIST TO THE WHITECHAPEL (L.C.C.) CLINIC

The object of this paper is to demonstrate the need for the complement-deviation test as a means of efficient diagnosis and treatment of gonorrhoea. Although much work has been done in Europe by R. Förster,[1] A. Cohn,[2] and P. Timoféeff,[3] in America by Kolmer[4] and Kilduffe,[5] and in this country by Thomson,[6] Osmond,[7] and Osmond and Oliver,[8] it is regrettable that the merit of the test is not more appreciated, and that it is, in consequence, insufficiently used. The opinions expressed below are based on the study of the clinical histories and serum reactions of approximately 7,000 cases.

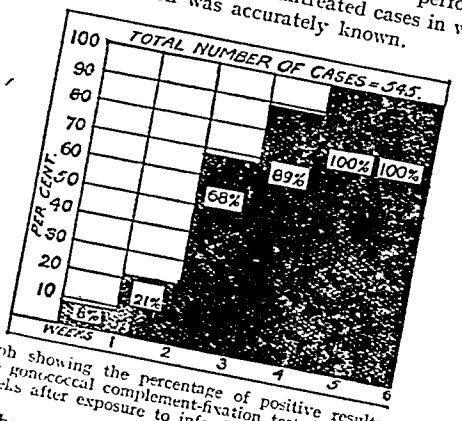
RATIONALE OF THE TEST

The test, [illegible] the technique of which I have described elsewhere,[9] is highly specific (0.03 per cent. false positive in 1,133 cases[10]), but it must be clearly understood that it demonstrates the presence or absence of specific gonococcal antibody in the blood, and not the presence of gonococci in the tissues. Thus all results must be read in conjunction with the clinical history, and judgement accordingly. The prognosis depends on: (*a*) the action of the specific antibody, (*b*) the anatomical spread of the infection; (*c*) the reaction of the disease; (*c*) the reaction of th

tissues to the presence of gonococci; and (*d*) the stage of the infection at which treatment is instituted and the efficacy of therapeutic action.

AGE OF INFECTION

In order to estimate the stage of infection at which a positive reaction may be expected the following graph was constructed from the results of the tests performed for the first time on serums from untreated cases in which the age of the infection was accurately known.



Graph showing the percentage of positive results given by the gonococcal complement-fixation test during the first six weeks after exposure to infection.

From the above it will be seen that the likelihood of obtaining a positive result varies, within limits, directly with the age of the infection. Thus, in the first week after exposure to infection only 8 per cent. (14 out of a total of 177 cases) of positive reactions were obtained. There is a rise to 21 per cent. (48 positives from 228 cases) in the second week, 68 per cent. (62 positives from 91 cases) in the third week, 89 per cent. (42 positives from 46 cases) in the fourth week, and 100 per cent. in the fifth and sixth weeks. From these figures it is apparent that the diagnostic value of the test is greatest from the third week onwards. On the other hand, positive cultures and smears are obtained during the first three weeks of infection. In "subacute" infections often present problems for accurate diagnosis, particularly in cases in which the patient has attempted to cure himself, but has only succeeded in driving the gonococci into the deeper tissues and at the same time has grafted a secondary infection on the original gonorrhoea.

ANATOMICAL SPREAD OF DISEASE

This depends on the age of the infection, the reaction of the tissues, and the treatment, if any, adopted. Case histories show that when, in the male, the posterior urethra, prostate, vesicles, or the epididymes, and, in the female, the cervix, cervical canal, uterus, or Fallopian tubes become involved, a positive reaction is the rule.

REACTION OF THE TISSUES

It appears that the tissues respond somewhat slowly to the presence of gonococci, although antibody production commences during the first week of infection. Three cases which were exceptions to this rule were met with during the course of this investigation, and one may be quoted.

The patient was an unemployed domestic servant, aged 22, who when first seen, complained of a vaginal discharge of 14 days' duration, and admitted a definite exposure to infection. Gonococci were identified in smears and cultures, but the complement-fixation reaction was negative. After four days' routine treatment, gonococci were obtainable from the cervical secretion, but the complement-fixation reaction was negative. A course of gonococcal detoxicated vaccine was given over a period of two months, and at the end of this time gonococci were still present in both the urethra and the cervical canal, whilst the complement-fixation reaction remained negative. Routine treatment was continued until eight months after the original infection, when the patient was clinically cured, whilst bacteriological and serological investigation proved to be negative. Thus, throughout the disease, no antibody production was demonstrable, in spite of a definite infection of the cervical canal by the gonococcus and of the administration of large doses of gonococcal vaccine.

EFFECT OF TREATMENT

If adequate treatment is adopted early—that is, during the first week of infection—the reaction may become only weakly positive, or it may even remain negative throughout the course of the disease. These cases are usually rapidly cured, and the lack of antibody production (hence a negative serum reaction) is possibly due to the anatomical localization of the infection affording less opportunity for interaction between the gonococci and the tissues.

Once the reaction has become positive it does not weaken until the infection has been eradicated from the body. After the acute stage of the infection has passed it is usually difficult to demonstrate foci of infection by means of smears or cultures, especially in the female. Moreover, the presence of pus alone is not necessarily due to the gonococcus, and unless a complement-fixation test is performed there is no certain means of ascertaining whether the inflammation is due to the gonococcus, to a secondary infection, such as staphylococci or coliform bacilli, or to a chemical irritation. As soon as the gonococcal infection is cured, the test, although positive, tends to weaken, and in about three to four months a clean negative result is usually obtained. To demonstrate this, 50 cases of uncomplicated gonorrhoea were followed through from the onset of the disease to the point at which the reaction became negative, monthly serum tests being performed in each case.

TABLE I.—*Showing Relationship between Clinical Condition and Serum Reactions of 50 Cases of Uncomplicated Gonorrhoea*

Months after Infection	Clinically Cured	Serum Reactions		
		Negative	Doubtful	Positive
1st month	0	0	0	50
2nd month	13	7	5	33
3rd month	29	20	2	29
6th month	50	50	0	0

The results tabulated above show that none of the 50 cases investigated were clinically or serologically cured one month after infection. At the end of the following month, of the 13 cases that were clinically cured 7 gave negative, 5 gave doubtful, and 1 gave a positive reaction. Three months after infection 29 cases were clinically cured, and of these 20 gave negative reactions, 2 were doubtful, and 7 still resulted in positive reactions. Finally, six months after infection, 50 cases were clinically and serologically cured.

When gonococcal complications such as salpingitis or arthritis occur, more strongly positive reactions than usual are obtained, and in these cases quantitative tests are performed by using increasing dilutions of serum up to 1 in 100 (the standard dilution in test being 1 in 5). When a cure is established there is a persistent weakening of the positive result until a clean negative result is recorded—for example, ++ (1 in 60), ++ (1 in 30), ++ (1 in 10), +±, ± to negative. If there is no reduction in the strength of the reaction in spite of apparent

clinical cure, it is definite evidence that an active focus of infection persists. In cases where vaccines have been used in an attempt to stimulate the tissues to combat the disease during the course of treatment a positive reaction (for example, +) may be converted into a strongly positive reaction (for example, ++, serum diluted 1 in 40), but this increase usually drops to the original strength (+) within six weeks after suspension of the vaccine treatment. In about 50 per cent. of cases treated by gonococcal vaccine no increase in the amount of antibody is recorded by the test.

The test is applicable to children as well as to adults. With the co-operation of Dr. Dorothy Brown, medical officer at Coldharbour House, Croydon, some 47 cases of vulvo-vaginitis in children were investigated. Gonococci had been demonstrated during the course of the disease in 42 of these cases. When the complement-fixation test was performed, 29 gave positive results, 7 were weakly positive (6 were old-standing treated cases and 1 an early case of a week's duration), and 6 which gave negative results were clinically cured at the time of the test. The remaining 5 cases in which no gonococci had ever been found gave negative reactions. Therefore it would appear that results similar to those found in the adult are to be obtained in children.

EXCEPTIONS

During the course of this investigation three types of exception to the general rule were met:

Failure to Produce Antibody.—Three cases of gonococcal infection, with no production of antibody, repeatedly gave a negative complement-fixation reaction.

Intercurrent Infection.—In one undoubted case of gonorrhoea (gonococci isolated in smears and cultures, complement-deviation reaction ++) of two months' duration, the patient during treatment developed a sore throat (Wassermann reaction negative). This was followed a few days later by an arthritis of the left elbow, which clinically was not typical of a gonococcal arthritis. A short-chained streptococcus was cultured from both the throat and the elbow.

"*Cross Fixation.*"—In two cases the possibility of false positive reactions being given by the antibodies of *Micrococcus catarrhalis* could not be excluded. The occurrence of this so-called "cross fixation" has been pointed out by Oliver[11] and might result in a false positive reaction being given by the serum of a patient cured of gonorrhoea, but suffering from a catarrhal condition of the nasopharynx. An attempt was made to deal with these cases by means of monthly parallel quantitative tests on the serum of the patient demonstrating a steady progressive fall in the strength of the positive reaction when using a gonococcal antigen, while the strength of the reaction when using an antigen of *Micrococcus catarrhalis* remains constant. This is shown in the following table, in which the strength of the highest dilution of serum which gave a positive reaction is tabulated.

TABLE II

Monthly Reactions	Highest Dilution Serum giving a Positive Reaction	
	Gonococcal Antigen	Catarrhalis Antigen
1st reaction	1 in 60	1 in 80
2nd reaction	1 in 50	1 in 80
3rd reaction	1 in 10	1 in 80
4th reaction	1 in 5*	1 in 80
5th reaction	Partial positive at 1 in 5	1 in 80

* Standard dilution of serum used in the test.

While this is not regarded as proof of an infection by *Micrococcus catarrhalis* as opposed to one by the gonococcus, it is at least suggestive, although experience of such cases is very limited.

INTERPRETATION OF RESULTS

The interpretation of results must be correlated with the clinical history if a reliable opinion is to be given on the result of a test. The usual notation is used:

++ or +± = strongly positive
\+ = positive
± = weakly positive
− = negative

A strongly positive or positive result is definite evidence of a gonococcal infection, and it may be taken that the posterior urethra, etc. (or in the female the cervical canal), have become involved. A weakly positive result (±) is obtained in (*a*) early cases (one to three weeks after infection), (*b*) old-standing cases which clinically are cured, but in which enough "residual antibody" is still present in the serum to cause this result. A negative result obtained when gonococci are exhibited in the secretions should be regarded as (*a*) an early infection of under twenty-one days' duration, (*b*) if over twenty-one days' duration, an unusual case in which the defensive mechanism of the body has not responded to the infection and in consequence no antibody has been formed. A negative result obtained when no gonococci are demonstrable indicates that the case is (*a*) cured, all "residual antibody" having been eliminated from the blood, or (*b*) not a gonorrhoeal infection.

CONCLUSIONS

1. The complement-fixation test for gonorrhoea as performed by this method is as useful in the diagnosis and treatment of gonorrhoea as the Wassermann reaction is in syphilis.

2. No patient should be discharged as cured of gonorrhoea unless the blood serum gives this negative complement-fixation reaction.

3. A negative result, if read in conjunction with the history and other pathological findings (for example, smears and cultures), has a definite significance.

4. A positive reaction is definite evidence of a present infection by the gonococcus or of an infection in the immediate past.

5. If the test were performed on the serum of patients suffering from arthritic joints, tenosynovitis, iritis, and particularly in women suffering from abdominal pain of obscure origin, fewer errors in diagnosis might be made.

6. The test should be instituted as a routine procedure in all venereal disease clinics.

I wish to thank Colonel L. W. Harrison for permission to publish that portion of the work done at St. Thomas's Hospital V.D. Clinic while I was acting as assistant pathologist to the department; Dr. Anwyl Davies, director of the Whitechapel Clinic; and the medical officers of both clinics for their co-operation and help.

TREATMENT OF CARBOLIC ACID POISONING

BY

O. S. GIBBS, M.B., CH.B.

FORMERLY PROFESSOR OF PHARMACOLOGY, DALHOUSIE UNIVERSITY, CANADA; VISITING LECTURER IN PHARMACOLOGY, JOHNS HOPKINS MEDICAL SCHOOL, U.S.A.

The carbolic acid group constitutes one of the most popular suicidal poisons, and thus possesses a clinical interest to any medical man, especially in regard to immediate and proper treatment. Reference to many of the works on toxicology is often disappointing, since the essential features of treatment are apt to be obscured by a discussion of impracticable, or even useless, methods. Situated in a laboratory one rarely comes in contact with such cases except by consultation, and thus only at a late stage. Two recent cases of this type, however, raised the question of the most practical procedure that could be adopted by the physician in charge.

There is no need to repeat the well-known details of this form of poisoning. Briefly stated, carbolic acid is a quite non-specific poison, causing loss of function and eventual cell death to any tissues with which it may be brought in contact, if it is sufficiently concentrated or acts over a sufficiently long time. Three places are particularly subject to damage. The first is the site of absorption, be it skin, gastro-intestinal tract, or any other area. If the acid is concentrated, coagulation of the tissues will ensue here, leading to mass death of the cells. After absorption the central nervous system is particularly susceptible, as with any fat-soluble depressant, leading to the typical descending type of functional inactivity, with final failure of respiration. Since the kidneys deal with the poison in a relatively more concentrated form, and over a longer period, in their work of elimination, they are therefore very liable to damage, and this constitutes a danger which is very serious. That carbolic acid is a general tissue poison must not be lost sight of, however, for in any case of poisoning, especially if functional weakness or damage previously existed, other organs may be predominantly affected. The liver and heart are of particular interest.

As with most poisons, the problem of treatment divides itself into three parts. The first and most important aim is to limit absorption; secondly, to help the body to withstand the effects of the poison; and thirdly, to assist in its elimination. It is in regard to the first and most urgent problem that I venture to suggest a form of procedure that has the merit of simplicity, and is probably as effective, while it is certainly as safe, as any other recommended method.

The treatment is based on the fact that carbolic acid is much more soluble in oil than in water, and thus readily leaves a watery medium for one of oil, in which it remains pharmacologically inert. In this connexion I may recall the established fact that carbolized catheter oil has no virtue as an antiseptic. It would appear, therefore, to be sound treatment to apply oil freely to the site of absorption; thus, in the case of carbolic acid burns, washing in oil followed by soaked oily dressings is a logical proceeding.

When the acid has been swallowed an immediate administration of a large quantity of oil to the stomach contents would certainly render unabsorbable much of the acid. The most suitable substance for this purpose is ordinary medicinal liquid paraffin, which takes up the acid efficiently, and is entirely non-absorbable even by damaged mucous membrane; nor is it rendered absorbable by digestive processes; in this it possesses a great advantage over vegetable or animal oils, which are occasionally recommended as an adjunctive treatment. The use of this oil in any corrosive poisoning is sound, because not only will it allay irritation by mechanical means, but, as an unabsorbable oil, it readily assists its own elimination along with anything that may be dissolved therein. The effective dose would have to be large—at least half a pint (200 c.cm.), and as much more as one could induce the patient to take. Administration of the oil would not invalidate the use of the wash-out tube, though it would undoubtedly render this somewhat questionable proceeding even more messy. In cases where lavage is carried out, oil might with advantage be readministered prior to withdrawing the tube.

Too much stress cannot be laid on the fact that carbolic acid very rapidly penetrates tissues, especially unprotected tissues, and that even a short delay may be enough to affect the treatment adversely; thus the administration of paraffin has a great practical advantage over the wash-out as a primary method, since the time factor is much lessened. Treatment would then be continued by the use of repeated doses of magnesium sulphate according to the modern method, which is founded on the sound basis of retarding absorption and facilitating elimination from the bowel.

It is fairly well known that if pure carbolic acid is immediately wiped off the skin with pure alcohol a burn may be escaped. The reason for this is that the skin grease may temporarily hold up penetration of the acid, and the alcohol removes both. I had the interesting experience of seeing this idea extended to the use of alcohol dressings, the result of which was that the patient had become completely comatose and remained so for twelve hours. This was not surprising, since it would be difficult to devise a method more favourable to absorption. Alcohol is one of the few substances directly and readily absorbed from the stomach; furthermore, it may actually cause the absorption of drugs not otherwise taken up by this viscus. The use, then, of dilute alcohol as a wash-out medium, recommended in certain books, seems to be based on an imperfect understanding of the facts, and also appears a needlessly dangerous procedure.

In regard to the remaining treatment I have little to add to existing knowledge, though greater emphasis might profitably be placed on the conception that the patient has all his functions seriously impaired, and thus should be treated with the same care that severe surgical shock or anaesthetic poisoning demands. Prolonged journeys, inadequate provision for warmth, or any other cause of functional fatigue, should be rigorously avoided. Large amounts of fluid are indicated in order to facilitate the work of the kidneys, and thus should be administered by other routes than the gastro-intestinal for at least forty-eight hours when the poison has been swallowed, since absorption is not desired in this area. Alkalis seem definitely beneficial, but at least 3/4 oz. (20 grams) should be administered with the fluid during the twenty-four-hour period. High fluid intake should be continued until the urine is carbol-negative.

Dangerous symptoms can only be treated according to general principles. Caffeine is the best respiratory stimulant. In view of the fact that I have read in this *Journal* two discussions on morphine and heroin poisoning in which no mention of caffeine was made, it may be pointed out that pharmacological evidence shows that caffeine is the best respiratory stimulant in these conditions, as well as probably in any other. One very good reason for its use is that caffeine has no dangerous secondary effects in large therapeutic doses, providing the simple precaution of slow injection is adopted. The same cannot be said for either strychnine or lobeline. In animals poisoned with morphine I have found lobeline neither so satisfactory nor so reliable as caffeine.

Strychnine is a valuable drug, since it combines a powerful action on the vasomotor system with the property of stimulating the liberation of adrenaline. This latter substance has a direct stimulant action, not only on the vessels, but on the heart. Thus, while strychnine has no direct cardiac action of value, it may act as a stimulant to the heart through this mechanism; which is an interesting sequel to an old fight between clinicians and pharmacologists, in that both are now shown to be justified.

For continued cardiac action one of the digitalis bodies is indicated, strophanthin being probably the most convenient where the oral route is contraindicated. Strophanthin and caffeine are best administered intravenously in such cases, or for urgent need.

Summary

1. The use of liquid paraffin is advocated for carbolic acid burns.

2. The immediate administration of a large dose of liquid paraffin is advocated as the primary treatment of oral carbolic acid poisoning.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

TWELVE-YEAR-OLD ECTOPIC PREGNANCY

The following case of a woman who carried a dead full-time foetus for twelve years in her abdominal cavity, and had three normal deliveries of healthy children before its removal, seems of sufficient interest to publish.

A Chinese woman, aged 34, was admitted to the Wuhu General Hospital (after walking ten miles) complaining of abdominal pain and difficulty in micturition. There was no vomiting, but she felt feverish and was unable to sleep. Her temperature was 101° F.; pulse 100. Bowels opened regularly every day. These symptoms had existed for fifteen days; previously she had been quite healthy.

The patient had had no past illnesses. She had been married for fourteen years and had three children—all normal deliveries—alive and well, aged 9 years, 5 years, and 9 months respectively. No miscarriages had occurred. She had been unable to feed any of the babies as she had no milk. Menstruation, of three days' duration, was regular at thirty-day intervals.

On examination of the abdomen a mass presented, the size, shape, and position of a seven months' gravid uterus. She showed no concern about this, stating that it had been there for twelve years. Evidently it had grown to its present size in a few months, and had never altered since or given any symptoms. During pregnancy it moved upward and to the right, returning to the mid-line after delivery. On palpation the mass was clearly defined, except below, where it was continuous with the pelvic organs. It was hard, immovable, and the skin over it freely movable. It was tender to palpation all over; tenderness also extended into the epigastrium and right hypochondrium. Bimanual vaginal examination showed a low cervix, while continuous with the upper pole of the uterus, and apparently attached to the right appendages, was the hard, tender, immovable tumour. A provisional diagnosis was made of (*a*) fibromyoma, (*b*) right ovarian cyst. Urine was passed normally with straining; catheterization produced a few ounces of residual urine.

Abdominal pain gradually grew worse, and a week after admission it was decided to operate. Under general anaesthesia the abdomen was opened by a mid-line incision, and on opening the peritoneum a dark brown mass was seen to occupy the greater part of the abdominal cavity, while surrounding it on all sides were adherent coils of slightly inflamed intestines and omentum. The mass was extremely hard in parts, while in others the finger sank into decomposing tissue with a flow of dark brown fluid. Fears were entertained that it might be a malignant growth, and the advisability of continuing the operation was considered. However, the separation of adherent coils was started in the easiest part, and on isolating the smooth curve of a foetal spinal cord the nature of the tumour was realized. The foetus was lying in the right occipito-posterior position in an immensely dilated right tube. After dividing adhesions for an hour and a half it was possible to apply a clamp along the right side of the uterus and remove the foetus, with the tube and appendages. The placenta was adherent to the right tube and anterior abdominal wall, and was scooped out with the hand.

The wound was closed in layers, with a drainage tube in the pelvis, and the patient made an uninterrupted recovery. She was discharged home quite well in a month's time.

After operation the following story was obtained from the patient. Twelve years ago, when the lump grew, she thought she was pregnant, and when the time came for delivery pains started, but nothing happened. After three days she was told by a Chinese medicine man that she had not been pregnant, whereupon he needled the lump, and told her she would have it for the rest of her life. The story was verified by her husband.

An *x*-ray of the removed tumour is reproduced.

X-ray of tumour removed from the abdomen of a Chinese woman, where it had remained for twelve years.

Ectopic pregnancy going to full term is rare, and the omission of the condition in the differential diagnosis of this case is perhaps excusable.

I am indebted to the American Free Church Mission authorities at Wuhu for inviting me to operate at their hospital during three weeks' residence in the port, and to Dr. Watters, the medical superintendent, who gave valuable assistance during the operation in this case.

W. WARD DARLEY, M.R.C.S., L.R.C.P.
H.M.S. *Gannet*, China Station.

PUERPERAL INVERSION OF UTERUS

Dr. Noel Hypher records a case of acute puerperal inversion, in the *Journal* of August 2nd, 1930 (p. 179). I had a similar case this year, the details of which I now record.

The patient, a fisherman's wife, aged 29, was confined on January 4th with her first baby. As the labour was

prolonged, and the patient was getting exhausted, my assistant, Dr. Muriel Rippin, delivered with forceps, whilst I administered the anaesthetic. The placenta did not follow, and Credé's method of expression was tried and failed. Finally, as there was considerable haemorrhage and the woman showed signs of collapse, I extracted the placenta manually. I found it definitely adherent. After extraction the patient got much worse, and some slight bleeding continued. All the usual methods of treating shock were employed, and she gradually recovered, but still remained in a very weak and serious condition. Before leaving I made another internal examination, but, beyond feeling a big, oedematous, patulous os, noticed nothing abnormal. Dr. Rippin and I both felt the fundus, which appeared to be tightly contracted, but possibly smaller and rather lower than usual.

On the second day the patient seemed much better, and the fundus, which was felt daily, seemed to be involuting rapidly; no indentation was felt. On the fourth day the patient said she felt perfectly well, and had a cooked dinner. Temperature normal, pulse about 80. On the fifth day the fundus could only just be felt above the pubis, and the patient did not seem quite so well, with a little rise of temperature and a slight discharge.

On the sixth day the patient was worse, although she maintained that she felt well. Temperature 101° F.; more discharge. An internal examination revealed the whole of the uterus to be in the vagina, completely inverted. It was difficult to know what to do. It was suggested to leave it till it sloughed off, as seemed to happen in a case with recovery, recently recorded in the *Journal*. I decided to replace it at once. This was done under an anaesthetic, after cleansing, with very little difficulty. The vagina was packed with gauze and daily douched. The woman got quite well, and was up and about under the month.

I consider that the top of the fundus may have been drawn in by the adherent placenta during manipulation, and then the uterus contracted on this portion, gradually becoming completely inverted like an intussusception. I find that Matthews Duncan, in Taylor's *Midwifery*, states this is what usually occurs in these rare cases (1 in 190,000 confinements). But, on the other hand, the inversion may take place at the cervix; the lower part, yielding first, is rolled out.

In twenty-six years of practice, with plenty of midwifery, I have only once before seen a case of inversion. That was a case to which I was called in from the street while on my rounds. Here the whole uterus was outside the vagina, bleeding profusely, the placenta still adherent. The woman was moribund, and died before I could do anything to help her. In this case, I think the inversion was most probably caused by excessive suprapubic pressure applied by the midwife.

Lowestoft. DUDLEY W. BOSWELL, M.D., D.P.H.

Reports of Societies

GROWTH IN CHILDREN

The meeting of the Medical Society of London, on March 23rd, was devoted to the subject of growth in children, considered clinically, radiologically, and histologically. Dr. R. A. YOUNG was in the chair.

Dr. H. A. HARRIS, in introducing the subject, gave particulars of some observations which had been made in various departments of University College Hospital. To his mind the term growth conveyed something more than height and weight. It comprised the gradual development from the early ovum to the senile body. It included the acquirement of new functions, fresh responses to environment, and the unfolding of new patterns of behaviour. To an intelligent person a baby was of interest, not because it weighed 20 lb. at 12 months, but because it was a creature of various activities. Not only was the child growing from the start of life, but it was also gradually dying. At the same time as the growth pattern was evolving, certain parts of the child were undergoing a form of localized death. He had used for some time as a check on his own observations the well-known table which roughly indicated the first year of life as the first springing-up period, the second to the fourth year as the first filling-out period, the fifth to the seventh year as the second springing-up period, the eighth to the tenth year as the second filling-out period, the eleventh to the fifteenth year (adolescence as distinct from neutral childhood) as the third springing-up period, and the sixteenth to the twentieth year as the third filling-out period. The age divisions differed in boys and girls, but the change from the springing-up periods to the filling-out periods was very well marked. Dr. Harris also showed the curve based on the work of Scammon. This demonstrated, separately, curves for skeletal growth, neural growth, lymphoid growth, and genital growth. The nervous growth of the child was strikingly different from the skeletal growth. A boy at 7 took almost the adult size in hats. The growth of the brain was remarkably precocious. The lymphoid growth shot up to a maximum at about the age of 10 to 12, and then fell away. Genitally there was very little growth after birth until the immediate pre-puberty period. Altogether, height and weight gave a poor idea of growth unless the child could be viewed from the point of view of his neural, lymphoid, and genital development. Even all these curves together presented but a very imperfect picture of growth in the child, for every organ and tissue—one might almost say every cell—had its own peculiarities at different age periods. He drew attention to some queer exceptions to the order of the four groups he had mentioned. For example, the uterus lost weight from birth until the pre-puberty stage, and the suprarenal lost its birth weight and did not regain it until puberty. If one took the endocrine organs as a group, there was no evident correlation between the pituitary, the pineal, the thyroid, and so on. An extreme type of precocity in growth was furnished by the head of the human foetus at twenty weeks, when the superior semicircular canals were already marked out with ossification around them, the size being the same as in the adult. Any disorder of growth in the internal ear, therefore, must date before the twentieth week of foetal life. One could take organ after organ and demonstrate either precocity or delay.

Turning to the curious contrasts among animals, Dr. Harris said that the guinea-pig at birth showed a stage of development equal to that of the 7-year-old child—it was too old at birth to get rickets—while the rat, on the other hand, was born a very immature infant. The colt ran about directly after birth, while the kitten was helpless. The parent polar bear weighed half a ton, but its two cubs each weighed only 3 lb. at birth. Not only was the newborn guinea-pig equivalent to a 7-year-old child in respect of ossification, but its brain was almost as large as its mother's. From all these facts it appeared that growth was a very complex phenomenon. The fundamental growth curve was very far from furnishing any satisfactory explanation. In all the experimental laboratory animals there was no trace of the succession of springing-up and filling-out periods which were seen in the human child. In dogs, cats, and rabbits the growth curve tended to be uniform in type. The dog raced through its childhood, without any of those spells or

periods of delay characteristic of the human being, and became sexually adult at 1 year.

Dr. Harris then went on to discuss the processes of growth in bones, pointing out three distinctive stages: in the first, origin of cartilage, with proliferation of cells; the second, a process of calcification and senescence of cells, with some alteration in the intracellular material; and the third, the removal of the calcified cartilage and the laying down of new tissue in the shape of bone. The first of these three processes was a vegetative one, concerned with breeding, and the third was an animal process, with special function, as distinct from mere proliferation. The growth of cartilage depended almost entirely upon growth-promoting water-soluble substances, the calcification of cartilage on vitamin D, and the production of a working bony tissue on fat-soluble vitamin A, which guaranteed the soundness of the differentiated tissues. He showed many interesting sections illustrating bone formation, and again pointed out the great complexity of the question of growth. To him the whole story of evolution was wrapped up in the problem of the extent to which the specialized differentiated tissue overcame the merely vegetative proliferating tissue—the substitution of increased function at the expense of breeding. The complexity of the subject was increased by the fact that nature had curious variations. An excellent example of it was furnished in the nervous system. The brain grew almost to adult size in seven years, but in addition there was the tremendous complication arising from specialized precocities such as the internal ear. There was no philosopher's stone represented by some so-called growth-producing food which was going to remedy that which nature had taken a few million years to bring about.

Dr. GARDINER HILL described a series of cases of children who had been sent to him during the past few years for defective growth. It seemed possible to classify these children into those who were normally proportioned and those who were disproportioned. With the former, one found, if one followed them up for a period of years, that the majority developed quite normally. Most of these children were either prematurely born, had a family history of delayed development, or had suffered from some cachectic illness like diabetes, and growth had been delayed, but ultimately most of them developed into normal individuals, though perhaps "on the small side." The second group really consisted of the pathological cases, and could be divided into two: those who had suffered from one of the various forms of rickets, and those in whom there was some endocrine disorder. He subdivided the rachitic children into four types, and the endocrine group into three—namely, cases of thyroid deficiency, cases in which the anterior pituitary was destroyed, and cases in which there was some deficiency of the sex glands. He also showed some interesting cases of eunuchoidism. Radiography was helpful in the study of these cases, because, in the normally proportioned case, bone development was normal for the size of the child, but backward when compared with a person of normal size; in the rachitic group the typical changes of rickets were present; in the endocrine type bone development was backward, both for age and for size.

The PRESIDENT said that Dr. Harris's address had been so original and so fascinating that probably it had had the effect of discouraging discussion, members preferring to think about the points he had brought forward. Dr. Harris, as an anatomist, had shown how a living anatomy could be taught, as opposed to the dead anatomy of the student days of many of those present.

Dr. HARRIS said that his views on growth and bone formation were really very much in the melting-pot, and new facts were continually coming forward which threw considerable doubt upon his previously formed notions. What he had wanted to stress in particular was that there was no short way of tackling the problem of growth. There could be nothing rigid in the position taken up at present with regard to this matter. One practical point which could be stated dogmatically was that for many children in hospital the most efficient treatment for dietetic deficiencies was cod-liver oil, which was much better than far more expensive preparations.

THE VALUE OF LIVER IN TREATMENT

At a meeting of the Section of Medicine of the Royal Society of Medicine, held on March 24th, the subject of discussion was the value of liver in treatment. Dr. R. A. YOUNG, president, occupied the chair.

Dr. JANET VAUGHAN said that she had attempted to classify the conditions which had been extensively treated with liver with reference to the degree of response to such treatment. Anaemias which reacted to liver extracts were: idiopathic pernicious anaemia, sprue, pernicious anaemia of pregnancy, and pernicious anaemia associated with intestinal lesions. Secondary anaemia following haemorrhage was responsive to whole liver as opposed to liver extracts. Anaemias affected by whole liver and iron were the secondary anaemias associated with starvation, carcinoma, haemorrhage, and defective dietary in children. The anaemias irresponsive to liver were, in the first place, the simple achlorhydric anaemia, so common in middle-aged women, and which improved extremely well on iron therapy, and the secondary anaemias associated with leukaemia, sepsis, nephritis, the Banti syndrome, acholuric jaundice, cirrhosis of the liver, and scurvy. Aplastic anaemia was also unaffected, and the blood diseases which were irresponsive were haemophilia and purpura haemorrhagica. The anaemias of the first group, belonging to the pernicious anaemia syndrome, which were influenced by liver and stomach extracts, were characterized by a deficiency in the gastric digestion of protein and a megaloblastic hyperplasia of the bone marrow. Clinical and experimental evidence suggested that the effective principle in liver and stomach extracts was essential to normal development of the megaloblast, and was elaborated by gastric digestion of protein, the liver and kidneys probably serving as storage depots only. When, therefore, owing to faulty gastric function, this principle was lacking, the megaloblast, which was unable to develop, proliferated. In the second and third groups—namely, anaemias responsive to whole liver, and those reacting to whole liver and iron—megaloblastic hyperplasia did not occur, and extracts, therefore, which contained only the principle affecting megaloblastic tissue were valueless. The deficiency in these cases was possibly due to faulty absorption, dependent upon achlorhydria, of both iron and the second factor present in the whole liver. It was recognized that the isolation of the factor effective in pernicious anaemia would revolutionize the treatment in the first group, but certain principles applied to the technique of both oral and intravenous administration. The latter was ideal in acute cases, but as suitable preparations were not yet generally available, massive oral dosage was the best substitute. Conditions affecting the level of an adequate maintenance dose were: sepsis, nervous lesions, arterio-sclerosis, and iron and thyroid deficiencies. In treating a severe case of idiopathic pernicious anaemia, the essential point was to give as large a quantity of the effective material as possible in the shortest time. It was necessary to keep the red cell count over 4,000,000. Liver therapy would be of real value when those conditions in which it could be expected to act in a satisfactory manner by relieving a known

deficiency were realized, and, secondly, when the essential importance of an adequate dose was thoroughly grasped. An adequate dose in many cases would probably appear to be an absurdly large dose.

Dr. S. C. DYKE said that liver had now taken a well-recognized place in the treatment of pernicious anaemia, but of all diseases pernicious anaemia was probably most frequently diagnosed when it was absent and not diagnosed when it was present. He desired, therefore, to say a few words on diagnosis. There were three points to be borne in mind: (1) an average increase in the size of the red cells; (2) haemolysis; and (3) achlorhydria. For the examination in respect to the first of these he advocated one of the modifications of the Pijper method (*British Medical Journal*, 1929, i, 635), by which a film of blood was used as a diffraction-grating. He thought that that should not be omitted from any case in which there was doubt. The question of haemolysis depended upon the colour of the skin, the presence of bile pigments in the urine, and a positive van den Bergh reaction in the serum. Evidence as to achlorhydria might be obtained by means of the fractional test meal. It was advisable to include this in all cases where it was desired to establish a certain diagnosis. With regard to free hydrochloric acid, it was necessary to bear in mind that a few cases of what was obviously true pernicious anaemia, giving the full blood picture, had been recorded in which a fractional test meal had shown free hydrochloric acid present. Pernicious anaemia depended upon some failure in the splitting up of protein in the stomach, but one was forced to the conclusion that although free hydrochloric acid was absolutely essential for the formation of the anti-anaemic principle, none the less pernicious anaemia might develop even when such free hydrochloric acid was present. As a final diagnostic test, one ought now to include the response to liver itself. It was possible that in certain cases of true pernicious anaemia the anti-anaemic principle of liver could not be made use of even when taken by the mouth. So far as treatment was concerned, to determine whether or not any given case would respond to liver therapy need not necessarily entail any long delay from a clinical standpoint. He would lay it down as a general principle that having diagnosed pernicious anaemia, and having initiated liver treatment, if one failed to find a definite reticulocyte response by the fifth day it was probably not worth while persisting in the treatment. With a high degree of anaemia to start with, the reticulocyte response might be very high. The actual estimation of the reticulocytes was not a difficult matter. A further early sign of response to treatment was an improvement in the colour of the patient. It was of the utmost importance that the anti-anaemic principle should be given in sufficient dose, and in his view a sufficient dose was equivalent to about half a pound of liver a day, as originally set out by Minot and Murphy. In the early stage of the disease blood transfusion might be called for, but he tended less and less to regard the transfusion of blood as being necessary. With the exception of hydrochloric acid, he had found no value from the continued use of the earlier remedies for pernicious anaemia along with the liver. With successful treatment there was a return to a normal blood picture, and not a modification of the red cells alone. The nervous manifestations frequently constituted the most distressing and the most persistent feature of the disease. The assessment of the value of liver in other anaemias than those of the pernicious type was a difficult matter, because these anaemias formed a large and heterogeneous class. In secondary anaemias he had found the treatment useful only in those cases due to haemorrhage—puerperal, gastric, from piles, and from ulcerative colitis. The effect was enhanced by iron. In chlorosis the treatment appeared to be useless, and in the leukaemias there was no effect on the white cell count, but the treatment appeared to assist in maintaining the red cell count.

Treatment by Hog's Stomach

Dr. JOHN F. WILKINSON said that about two years ago, with a view to following up the work of W. B. Castle (*Journal*, 1929, i, 1120) on the occurrence of achylia gastrica in association with pernicious anaemia, it had appeared to him that the gastric tissue would prove a very potent source of the active substance which was absent from cases of pernicious anaemia. He therefore looked round for a common source of supply, and the three that occurred to him as being most available were the stomachs of the ox, the sheep, and the *pig*. From later experiments he found that the stomachs of the ox and sheep did not possess the therapeutic value of the pig's stomach, and therefore he had confined his further work to that particular tissue. He administered to nine patients the raw uncooked hog's stomach, and they all gave a very good response—a very much greater response than he had anticipated. As long as they were in hospital he was able to keep them on this diet, and after discharge they were put on a desiccated preparation which he was himself making in the laboratory. Of these nine cases, one man was kept on raw stomach tissue the whole time; he had now had this patient under treatment for twenty-two months. The dose he originally gave him was about 250 grams per day whilst in hospital; he then gradually reduced the dose until eventually the man was receiving 1,000 grams per month. He took this amount in three days, and then took no more for the rest of the month. The dose was reduced to 750 grams monthly, but the red cells and haemoglobin fell, and therefore he increased the dose again to 1,000 grams. For obvious reasons, raw stomach was not convenient to administer to the bulk of patients, although it was the cheapest method of treatment he knew. It was certainly more palatable than raw or partially cooked liver. Desiccated preparations were more convenient, and he had been using these in the majority of cases. The normal initial dose in the severest case need not exceed 1 to 1½ ounces daily. As soon as response began, and the red cells increased to 4,000,000, the dose could be reduced to 1/2 ounce, and he had found that the average maintenance dose for the majority of patients was somewhere, varying according to the individual, between 1/3 and 3/4 ounce daily. It was extremely important that these patients should take an active preparation. He considered the use of hog's stomach under two heads: first of all, in connexion with pernicious anaemia, including the pernicious anaemia of pregnancy; and in the second place, in the other conditions in which liver was tried. In pernicious anaemia the immediate results were very similar to those obtained with liver, but rather more rapid. He had under observation at the moment 140 cases of pernicious anaemia on hog's stomach treatment, and of these, 108 cases had been on this treatment for a minimum of six months and a maximum of twenty-two months. There had been a definite relapse in thirty-one cases on the liver treatment, but on the hog's stomach treatment more than 92 per cent. were perfectly well and free from symptoms, and a further 6 per cent. were well, though still suffering from some lesser degree of nervous impairment. No single case in the whole of this consecutive series had failed to respond to hog's stomach, and two of the patients now had not taken any treatment for six months. He had had several cases, outside this series, of definite posterior lateral sclerosis without blood changes, and while every one of them had shown a blood response

within the region of 6,000,000 red cells, there had not been so far a great improvement in their nervous condition. Of the series of 108 cases, 22 patients had red cell counts of between 4,000,000 and 5,000,000; 85 had a count of over 5,000,000, and of these latter, 32 had over 5,500,000, and 13 over 6,000,000. He stressed the point that the treatment of pernicious anaemia should be continued—it should not be stopped without very careful consideration—and with this end in view it was very important that regular blood examinations should be made. On doing regular counts every four weeks, he had found that the slightest infection profoundly influenced the red cell count; even the common cold would send it down to the region of 3,000,000. At such periods it was advisable to increase the treatment, whether by liver or by hog's stomach. In regard to the other group of conditions (not pernicious anaemia), the result of hog's stomach treatment fell into line with the results obtained with liver. He mentioned two cases of epithelioma of the mouth; both patients had achlorhydria, and had blood pictures typical of pernicious anaemia. They were treated by hog's stomach. One of them did not do at all well, but the blood picture changed to that of the secondary type of anaemia. The second had done extremely well, and was undoubtedly very much better. Radium treatment was being given for the local lesion, but the blood changes were in keeping with those seen in the treatment of pernicious anaemia. Finally, there were a large number of patients who complained of vague gastro-intestinal disturbance. Examination of these patients frequently disclosed achlorhydria, very often an achylia, and in these cases the results of treatment with hog's stomach were remarkable. The symptoms were undoubtedly relieved, and the blood count certainly approached 5,500,000, sometimes 6,000,000, red cells.

Dr. WILLIAM BROCKBANK said that after the remarks of Dr. Wilkinson it might be thought that any further words on liver treatment must be in the nature of a funeral oration. But it was as well to remember that liver treatment had already saved many hundreds of people from death. It was immeasurably superior to the previous treatment by arsenic, which, although it did prolong the lives of patients with pernicious anaemia for a few months, or occasionally a few years, was more effective in preserving the bodies of the dead than in preserving the life of the living. Of the cases under his observation which had been treated by liver, quite 50 per cent., provided the diet had been strictly adhered to, had returned to normal health, and a further 15 per cent. could be added to this figure were it not for the persistence of neurological manifestations. The less the liver was cooked the better. In his experience all the patients who had cooked their liver to any great extent had relapsed. Most of the work had been done on whole liver, because liver extracts were more expensive and not so reliable. The patients were allowed to cook the liver very slightly, to remove the first unpleasant rawness. Symptoms of flatulent dyspepsia, often associated with diarrhoea, did tend to persist on the liver diet. Such patients were placed on a mixture of hydrochloric acid and pepsin—three parts of glycerin of pepsin, and one part of dilute hydrochloric acid—and they sipped this mixture, flavoured with orange juice, throughout their meals. This had never failed, in his experience, to relieve the symptoms of dyspepsia.

Dr. G. W. GOODHART had known a number of cases which appeared from the blood count to be typical pernicious anaemia, but did not produce the asymmetrical curve which was essential for diagnosis, and this was a possibility worth remembering in cases which did not respond to liver.

OEDEMA AND NEPHROSIS

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland held on March 13th, with the president, Dr. H. F. MOORE in the chair, Dr. A. G. THOMPSON read a paper on oedema and nephrosis. Four cases in which the nephrotic syndrome occurred were fully described. This syndrome consisted clinically of oedema and oliguria without any necessary defect of kidney function; from the biochemical aspect its main features were albuminuria, no evidence of nitrogen retention, a high blood cholesterol, and a diminution of the serum proteins which affected the albumin fraction more than the globulin fraction, with the result that the albumin-globulin ratio fell. The speaker outlined the progress of these cases and the effect of treatment, together with the results of frequent exhaustive blood examinations. In one of the cases death took place ar photomicrographs of the kidneys showed a pure, (almost pure, tubular degeneration. Dr. Thompson di cussed the causation of the nephrotic syndrome. Th picture presented by nephrosis was fairly definite, but th cause far less certain. It was possible that the caus might be external to the kidney—for example, primary change in the blood proteins. It might occu by itself or it might be a part of a glomerulo-nephritis.

The PRESIDENT said that he had recently had severa cases of nephrosis under observation, and in none of ther had there been any hypertension. This was curious, sinc it had been shown that in most cases there was som involvement of the glomeruli. The appearance of a fev red blood cells in the urine did not negative a diagnosi of nephrosis.

Dr. T. G. MOORHEAD noted that Dr. Thompson hac used a chlorine-free diet. He himself had long since discarded such diets, owing to the fact that there was no evidence of chlorine retention in the blood. The retention of chlorides in the body was probably due to the fact that oedema fluid was retained in the tissues. Dr. A. R. PARSONS was sorry to hear the President's statement that the glomeruli were sometimes involved, because this seemed to him to render it extremely difficult to differentiate the condition of nephrosis from that of glomerular nephritis. Dr. E. T. FREEMAN referred to a case recently under his care which had benefited greatly by treatment by novasurol, and said that novasurol and salyrgan were especially useful in cases of nephrosis. He regarded the presence of blood in the urine as distinctly against the diagnosis of nephrosis. Widal had recognized the fact that chlorides were not increased in the blood, even in cases in which there was practically no chloride excretion by the kidney. Dr. J. MOWBRAY thought that the new term "nephrosis" made the already existing confusion worse than ever. He failed to understand to what condition the term nephrosis should be applied. Should one apply it to the subacute condition which often followed acute nephritis, or to old-style chronic parenchymatous nephritis, or to both? Dr. R. A. Q. O'MEARA suggested that confusion arose because etiology had not been sufficiently considered. Acute nephritis could be produced either by bacterial toxins and chemical poisons or by toxic proteins arising within the body. Some of the abnormal conditions of the kidney occurring in pregnancy were of the last-named class. The condition of the patient depended upon the degree to which the different elements of the kidney were attacked. In nephrosis much protein was lost by the kidney. As a result, the fat reserves of the body were called upon. Imperfect metabolism of fat resulted in the production of cholesterol in excess, and finally the kidney tried to excrete this cholesterol.

Reviews

ACUTE INTUSSUSCEPTION

The latest addition to the new French Monographs on Paediatrics Series is entitled Acute Intussusception in the Infant,[1] and its authors, Drs. F. D'ALLAINES and J. ARMINGEAT may be congratulated on a valuable piece of work. In a little over a hundred pages they deal with every aspect of this important subject, giving a good survey of the literature—with more Anglo-Saxon references than usual in a Gallic product—and they rightly make the questions of early diagnosis and early operation the main themes of the book. They quote two principles which adequately summarize the whole matter: "signs of obstruction plus the passage of blood per rectum equals intussusception," and "every infant with obstruction who is passing blood per anum ought to be operated upon at once." The short chapter on etiology fails to give any adequate explanation for the occurrence of intussusception, and it is not quite in accord with English views to say that while 68 per cent. of all patients are under 1 year of age, 50 per cent. of cases occur before 6 months, since the usual period is surely the second six months of life. Apart from this small blemish the book can be thoroughly recommended, and the simple lesson it teaches would, if learnt by all practitioners, save an appreciable number of lives each year.

DISORDERS OF THE DIGESTIVE SYSTEM

In his preface to a *Practical Treatise on Diseases of the Digestive System*,[2] Dr. L. WINFIELD KOHN states that he proffers his book to "those who would supplement their knowledge of gastro-enterology" by "recourse to a thoroughly modern, scientific, practical reference book," a statement which can scarcely be said to disarm criticism. Dr. Kohn has had a wide experience of gastro-intestinal disorders in Baltimore, Philadelphia, and New York, and this is shown to advantage in some of his descriptions of the rarer diseases, as also in his discussion of gastroscopy and gastrophotography and in the wealth of excellent illustrations, mostly from *x*-ray photographs. He has attempted a very thorough treatment of his subject, commencing with anatomy and leading on through physiology, history-taking, objective findings, special methods of examination, clinical significance of findings, neurological considerations, and finally clinico-physiological considerations, to the actual diseases, which are first dealt with on page 423. This section is then followed by nearly 150 pages dealing with diet and therapeutics in general.

Such a plan, though perhaps theoretically sound, is apt to lead the unwary author into long and wearisome detail, and above all to tiresome repetition. Moreover, a book so constructed has disadvantages for reference purposes, since one finds part of the treatment of a disease under its own heading, part under diet, and part again under therapeutics. When, in addition to this, the author's knowledge of the scientific side is not always beyond question (a good deal of recent work with regard to such subjects as secretin, bile, jaundice, and secretion of chlorides by the stomach is omitted) and his style is vague rather than definite, rambling rather than concise, it becomes evident that a large part of the two volumes is tedious to read, and could profitably be cut down to a third of its present length. The subject of vitamins, for instance, is discussed in some detail under "deficiency diseases" and again under "vitamins" and further mentioned under "vitamin demands."

The description of diseases themselves, with their treatment, is the best portion of the book, though here again the author tends to wander from history to examination and back to history, and indulges in such sentences as "One of the most usual affections involving this particular part of the bowel is called appendicitis and also the condition termed perityphlitis" (p. 614), and such vague instructions as "The employment of various drugs such as morphine, atropine, and the various alkalis, including bismuth subcarbonate, sodium bicarbonate, calcium carbonate, etc., should be advised" (under the treatment of gastric ulcer). There are, besides, many serious omissions in a work which is intended as a textbook. For example, blood transfusion in the treatment of haematemesis, intermissions in the history of a gastric ulcer patient, saline purgatives in the treatment of various forms of colitis and dysentery, and the mercury-loaded bougie in the treatment of cardiospasm, are not mentioned. Moreover, in the long section on *x*-ray examination, Berg's technique for obtaining pictures of the mucous membrane (Schleimhautreliefbilder) is omitted. A bibliography follows each chapter, but its use is limited by the fact that in many instances the author has not been referred to in the text, and the title of his article is not given. Many of the illustrations also would gain by a suitable reference from the text.

After attempting to digest this mass of redundant detail, lacking in definite instruction, the reader will find a welcome relief in the lucid and concise style of Zachary Cope, who writes a brief but adequate chapter on the surgery of the gastro-intestinal tract. Altogether it seems to us that in this book there is a wealth of material which has been carelessly treated, and the prevailing impression is one of disappointment rather than of condemnation. It is to be hoped that in the form of a second edition this material (preferably condensed into one volume) will be supplied in a more palatable form.

OPERATIVE SURGERY

To Mr. CECIL P. G. WAKELEY has been entrusted the task of editing a fifth edition of Treves's well-known *Student's Handbook of Surgical Operations*.[3] It is by no means easy in a book of this size to cater both for the needs of a student attending a practical class in operative surgery and for the man in practice who wishes to revise his knowledge of operative technique. But it is evident throughout that Mr. Wakeley has kept this twofold object in mind, and with such a measure of success that a warm welcome from both classes of readers is assured for this new edition.

The arrangement of the book remains much the same, but a little alteration in the sequence of chapters, a considerable increase in the number of illustrations, and improved paper and type make it a decidedly more readable volume. For the first time such common orthopaedic operations as those associated with the names

[2] *Practical Treatise on Diseases of the Digestive System.* By L. Winfield Kohn, M.D., F.A.C.P. Vols. i and ii. Philadelphia: F. A. Davis Company. 1930. (Pp. 1125; 542 figures, 7 plates. 12 dollars net the two volumes.)

[3] *The Student's Handbook of Surgical Operations.* By Sir Frederick Treves, Bt., G.C.V.O., C.B., LL.D., F.R.C.S. Fifth edition, revised by Cecil P. G. Wakeley, F.R.C.S. London: Cassell and Co., Ltd. 1930. (Pp. xi + 535; 190 figures. 16s. 6d. net.)

of Stöffel and Steindler are described, laminectomy is both described and illustrated, and accounts are introduced of periarterial sympathectomy, avulsion of the phrenic nerve, and injection of varicose veins. A valuable description of "pre-operative ritual" precedes the rewritten section upon operations on the renal tract. Radium finds a place, not only as a subject for a new final chapter, but in the description of surgical treatment of cancer of the breast. Room for all these additions and many more has been found by the omission of obsolete procedures, such as some of the classical amputations of the lower limb, and of many of the comments introduced by Jonathan Hutchinson and now completely out of date. Quite properly Berger's fore-quarter amputation has been reintroduced. It will surely not be long before yet a further revision is called for, and when that time comes we hope to see the operation for ventral hernia put in its proper place, and not in the chapter devoted to strangulated hernia, and the suggestion eliminated that after treatment for a stricture of the urethra the patient "ought to pass a fair-sized bougie himself regularly."

A failure to find anything more important to criticize adversely should go far to commend the book as a well-balanced and trustworthy aid to teachers of operative surgery, their pupils, and the youthful practising surgeon.

OSTEO-ARTHRITIS OF THE HIP

Dr. DUVERNAY has collected his observations on chronic osteo-arthritis of the hip-joint[4] in a small, very readable volume, profusely illustrated with *x*-ray photographs, both direct and stereoscopic. His thesis is that two types may be recognized. In one of these there is no disturbance of the normal configuration of the hip-joint, while in the other this is grossly distorted. He maintains that in no case does the first develop into the second, and that they are two distinct clinical and pathological entities. The first is an example of chronic arthritis, such as may occur in any joint. The second is always the sequel of hip-joint anomalies which have arisen in childhood. These anomalies comprise: (1) congenital subluxations; (2) coxa plana; (3) coxa vara; (4) acute arthritis of the hip-joint. After adolescence these conditions may cease to give trouble and the patient may be able to undertake strenuous exercise, but in later life, toxaemias, strain, and infections cause a superimposition of arthritis. This is accompanied by the osteophytic outgrowths and distortions of both acetabulum and femoral head, so characteristic of malum coxae senilis. The author makes no mention of degenerative factors, or of the local arteriosclerosis described by Strangeways or of the areas of rarefaction in the bone demonstrable in the radiogram; but the symptomatology, diagnosis, and prognosis are adequately dealt with, and both medical and surgical treatment are discussed. In medical treatment the author favours diathermy, and wisely lays stress on the necessity for repeated visits to thermal stations for balneological treatment if good results are to be obtained. He points out that surgical procedures are admirable in theory, but in practice the patient is seldom able to stand the severe measures necessary to achieve the desired results. A useful discussion of the variations in form of the acetabulum appears in an appendix. Dr. Duvernay lays stress on the want of co-operation and common understanding between orthopaedists dealing with juvenile hip disease and physicians treating arthritis of the hip, and his book merits the close attention of both groups as well as of all those interested in this common malady of middle and later life.

[4] *L. [illegible] de la Hanche.* Par L. Duvernay. Paris: Masson et Cie. (Pp. 119; 51 figures. 40 fr.)

"CHILL"

Dr. MARIAN THORNETT'S suggestive treatise on the dangers and prevention of chill[5] is founded on observation of infants and growing children in London and on personal experience of both hot and cold countries. The thesis for which she invites criticism may be summed up in three propositions: (1) that a warm moist skin often causes chill from excessive evaporation, which is always dangerous in cold climates, and that it is the warm skin that feels the cold; (2) that mouth-breathing produces adenoids, and is commonly caused by the gasping of over-heated infants; (3) that the exaggerated susceptibility to cold in England is caused by over-clothing. It is not surprising, therefore, that the author has much to say in praise of a cool skin, believing that the serious danger of over-heating the skin in changeable and windy climates has not been sufficiently recognized. Even an almost imperceptible perspiration may cause great susceptibility to cold. There is reason for her statement that if the skin is cool and dry, as it usually is in lightly clad persons, exposure to cold causes a favourable reaction. But if this is, within limits, a rule of health, it is obviously not applicable to many delicate persons. The east wind is admitted to be an unfriendly element in the English climate, and windproof cloaks are advocated as a good defence. Readers who are interested in the causation and treatment of catarrh and rheumatic affections will find useful suggestions in this little work, though some statements require modification—for example, the dictum that the heated skin bears cold badly. The whole question of the relation of the skin and of chill to the causation of these and other diseases is an attractive one, and still needs elucidation.

TREATMENT BY STARVATION

Cures by hunger or thirst, of which Professor GÜNTHER gives a systematic and carefully written account in his book on this subject,[6] are at present attracting attention in the treatment of diseases of metabolism. The practice of starvation is as old as history, and the widespread custom of geophagy was no doubt a mitigated fasting. Hippocrates taught the uses and dangers of hunger-cure, but gave no special indications for it; and Asclepiades was accustomed to prescribe a three days' fast. In his interesting historical chapters the author recalls the mediaeval practice of fasting and thirsting when syphilis was treated by deep potations of infusion of guaiacum and no other drink allowed. A century ago the Silesian peasant Priessnitz was treating chronic diseases by cold affusions and 2 to 5 litres of water by the mouth, while in the neighbouring village Schrot was denying all liquids but gruels.

The clinical indications for reduced diet and periodic fasting are here fully dealt with, and useful warning given—for example, in cases of high blood pressure with pallor, the diet should be reduced to nitrogenous food only; for florid persons all kinds of food should be reduced. In members of families liable to hypertension, periodic fasting is a main preventive. Among other indications are obesity, gout, diabetes, allergic states (many migraines), acute infective and febrile disorders, and dropsies. In all reduced diets variety is the great desideratum. A list of the international literature is appended.

NOTES ON BOOKS

The Hospital of the Protestant Episcopal Church in Philadelphia commemorates the seventy-fifth year of its existence by the issue of volume vi of its *Medical and Surgical Reports*.[1] It is not so unusual in the United States as it is in England for a hospital to be supported by members of one particular religious community. For instance, in Philadelphia itself and in New York there are Presbyterian hospitals, to name only two. This volume of 460 pages does credit to the medical staff who have provided the contents, and to the board of managers, whose liberality made provision for its publication. It includes articles on nearly fifty medical and surgical subjects, dealing with the past and present work of the hospital staff. It is obviously not possible to display in review to our readers any adequate abstract of so many subjects, but we may say in general that the essays are of high merit and considerable interest. In particular, we would commend those on fractures by Dr. Edward T. Crossan, and Drs. A. P. C. Ashhurst and Ralph S. Bromer; that on spastic palsy by Dr. A. Bruce Gill; and on infectious osteomyelitis by Dr. Bromer. Dr. Crossan compares the treatment of fractures in 1853 with twentieth century practice, and finds the chief differences are due to a better understanding of the mechanism of displacement, a better appreciation of the necessity for immediate reduction, the value of Listerism in compound fractures, efficient methods of extensions, and, last but not least, the proper use of *x* rays. But nearly all the essays are merely reprints from medical periodicals. For example, the important and freely illustrated paper of 73 pages by Drs. Ashhurst and Bromer, on fractures of the leg bones involving the ankle, is reprinted from the *Archives of Surgery*, in which it appeared as long ago as 1922. Dr. Bromer's article on "Infectious osteomyelitis: differential diagnosis" is none the less valuable for having appeared elsewhere in 1927.

Drs. M. MOSINGER and R. GRIMAUD have made some experimental investigations on the velocity of corpuscular sedimentation in chronic surgical cases at the Maringer Hospital at Nancy. They premise their observation by a clear summary of the available data on this reaction, with which the name of Fahroeus is usually associated, but which they prefer to call, after its original discoverer, "the reaction of Biernacki." The explanation of the variations in this reaction, such as the acceleration in septic and febrile cases, is still obscure. The effect of certain French medicinal waters in the hospital cases above referred to was more often than not a reduction of velocity—that is, a diminution of previous acceleration. Experiments *in vitro* were more inconclusive. Further investigation of the action of medicinal waters in chronic cases is advocated.

Synthalin B (Dodecamethylenediguanidine) in the Light of Laboratory and Clinical Research,[2] by Dr. HIRSCH-KAUFFMANN, is a short volume that comes from the Children's Clinic at Breslau. The author claims that it is untrue to say that synthalin appeared six years too late to be of value, and argues that this substance is a valuable remedy for the treatment of light cases of diabetes, and that a combination of synthalin with insulin is of value in the treatment of cases of moderate severity.

The fifteenth monograph supplement to the *British Journal of Psychology* consists of an essay, with appendices, on "The growth of visual perception in children," by W. Line, M.A., Ph.D. This embodies the results of a research carried out in the psychological

NOTES ON BOOKS

laboratory of University College, London, under the direction of Professor C. Spearman, F.R.S. It is published by the Cambridge University Press (price 12s. 6d.).

The War Office Memoranda on Tropical Diseases,[10] which was originally compiled by the late Sir Andrew Balfour, has now reached its fifth edition under the direction of Colonel W. P. MacArthur. Only minor changes have been made in this edition, such as the addition of new matter on sprue and yellow fever, and a general bringing up to date. It is essentially a brief clinical handbook which can be readily carried about in the field, and its scope embraces all tropical and subtropical diseases having a military significance. It is well printed and illustrated, but a number of unfortunate misprints have escaped correction. Some of the older drawings, too, could be usefully dispensed with or replaced by more modern ones.

The tenth edition of *The Motor Boat Manual*[11] contains two new chapters, one dealing with high-speed marine Diesel engines, and the other with metal boats. Since the last edition of this popular handbook was issued about two years ago much progress has been made in the design and construction of hulls and engines. All the new types of inboard and outboard engines developed recently are examined in detail.

PREPARATIONS AND APPLIANCES

VIODAR

Viodar (Messrs. W. Martindale, 12, New Cavendish Street, W.1) is a new oily preparation, neutral in reaction, containing free iodine (strengths 1 in 200 and 1 in 1,000). It is recommended for local application and for internal administration. When applied externally the iodine is liberated by the warmth of the body.

EXTRACT OF HOG'S STOMACH

Byno eugastrol (Messrs. Allen and Hanburys Ltd.) is a highly concentrated extract of hog's stomach tissue intended for the treatment of pernicious anaemia. In 1929 various authors showed that feeding with stomach preparations produced a curative action in pernicious anaemia equal to, if not greater than, that produced by liver feeding. The makers state that eugastrol "is the result of prolonged experiments, including biological tests, which show that it has the full anti-anaemic potency of stomach tissue."

QUININE MILK POWDER

The tasteless quinine milk powder known as lacquin is a product issued by the firm of Cow and Gate. The chief purpose of this powder is to provide a tropical tonic food which will at the same time afford nourishment and prophylaxis against malaria. A teaspoonful of lacquin contains 2½ grains of quinine.

NEOTROPIN

Neotropin is a new antibacterial dyestuff that is being marketed in this country by Messrs. Schering Limited as a urinary antiseptic. The constitutional formula is 2-butyloxy-2.6-diamino-5.5-azopyridine ($C_{14}H_{19}ON_5$). The dye is water-soluble, and forms a light yellow solution.

Pharmacological experiments have shown that dogs tolerate doses of 0.12 gram per kilo of body weight for long periods, and that single doses of 0.5 gram per kilo are tolerated. These are far in excess of therapeutic doses. The drug is quickly absorbed and is excreted in the bile and in the urine. A concentration of 1 in 10,000 in broth kills many organisms, whilst a concentration of 1 in 1,000 kills all organisms tested in one or two hours.

Clinical tests have shown the efficacy of neotropin in cystitis, pyelitis, and pyelonephritis, and notably in gonorrhoea. It is claimed that the drug, on account of its unusual penetrative powers, is of particular value in treating the complications of gonorrhoea. Many urinary disinfectants have failed to fulfil their first promise, but the experimental and clinical results recorded in the case of neotropin justify the hope that it may prove to be a real advance in this difficult subject.

BALNEOTHERAPY IN RHEUMATISM

The relief of rheumatism by warm baths is traditional. It is surprising to the novice to find that the various "rheumatic" conditions respond very differently to the same form of treatment. As these are studied the possibility of a therapeutic classification comes into view, and it is not unthinkable that this may well be the beginning of a true differentiation of rheumatism.

Among physical remedies heat is pre-eminent in cold climates. In the medium of water it is very flexible, both in dosage and in time and place of application. In our issue of March 7th (p. 397) we published a full report of an address on the treatment of rheumatism by heat, the last of a series of communications in which, since his book on *Physical Remedies* in 1917, Dr. R. Fortescue Fox has pleaded for more precise and accurate use of baths and other external applications. A definite step forward was taken when the British Committee on Rheumatism, of which he was chairman, framed a scheme for a demonstration clinic in London,[1] where physical remedies should be systematically studied and applied to chronic rheumatic diseases—a scheme which was adopted and carried out by the British Red Cross Society. The existing state of this branch of practice in Continental countries, and the principles of modern physical treatment in rheumatic disease, have also been set forth in recent years.[2] In an address given to the Tunbridge Wells Division of the British Medical Association last summer the value of baths was expounded, with particular reference to their action as "artificial climates"[3]; and in his latest communication, given to the Southampton Division, Dr. Fortescue Fox carried this interesting thesis a little further into the domain of etiology. Discussing some of the abnormalities observed in the capillary circulation, he noted the frigo-sensitive condition which large numbers of rheumatic subjects exhibit, and the frequency of subnormal body temperature and of much greater depressions of surface heat. In his view these persons are, first and foremost, defective in the power of thermal adjustment. "For this reason true rheumatic disorders are aggravated in the colder months of the year. . . . Warm-blooded animals artificially chilled are very liable to infections. The mere reduction of body heat, [illegible] blement of circulation, and immobility favour the [illegible] on the [illegible] of micro-organisms." He therefore suggests, between [illegible] ortic [illegible] and physicians that true rheumatism is at its root a [illegible] primarily induced by the repeated [illegible] ments the close atten[illegible] those interested in this cobut subject also to subsidiary later life [illegible] g from food, infection, and endocrine dysfunction. The conclusion seems obvious that thermal treatment—precise, repetitive, and continuous—is the rational treatment of true rheumatism.

Can such a view of the curative value of heat be maintained, in face of the frequent disappointments attending treatment by baths? Against this doubt it is fair to remember that all remedies may fail, and the most admirable of operations. Indeed, the success of therapeutic methods depends as much on the skill of the operator as on the method itself, and it is not every man who can bend the bow of Achilles. It would seem, moreover, that in making use of heat in baths the aim may be missed in many ways: by overdose or underdose, or incorrect spacing, and especially by permitting the cumulative effects to be lost by intercurrent chilling. The principle of maintaining a thermal environment during a course of baths would, if adopted, profoundly modify the current practice in cold countries. In concluding his address at Southampton, Dr. Fortescue Fox enumerated five methods of thermal treatment, both preventive and curative, and graded in temperature, moisture, and movement, as appropriate for the different forms of rheumatic disease as met with in England. It will be noticed with interest that in some of these a certain grade of moist heat is regarded as a sufficient stimulus, to be accompanied by absolute rest. In others various degrees of heat and movement are conjoined.

The key of success in the use of all thermal remedies is held to be the study of individual reactions under treatment, especially in the early stages of disease, before the underlying circulatory disturbance has led to serious anatomical changes. It would certainly seem, from the evidence before us, that this should at all events be one of the main objectives of the new clinics for rheumatism in England; and it is not unreasonable to hope that an intensive study of cases under treatment will throw much light on the nature of rheumatic processes and on the means by they may be best controlled.

DISTRICT NURSING IN LOND

The domiciliary nursing of the sick in Londo from patients able to pay for a private nurse, is taken by district nurses employed by nursing tions, the larger number of which are affiliated Queen's Institute, and by the Ranyard Mission, with a few parish nurses. The local associati the Ranyard nurses number close upon four h and practically all of them have completed thre training at a recognized hospital school. In a *of District Nursing in the Administrative Co London*, prepared by Dr. Margaret Hogart published by the London County Council (1s.) useful particulars of this admirable service ha collected. The salary of the nurse employed district associations is £63 to £75, with board, uniform, and laundry, and of the Ranyard nu resident, £156 to £161, only uniform being

[1] *L'Action de Corrosifs de la Ha*[illegible] 12th, 1927, p. 893.
[2] [illegible] (Pp. 148, 51 figures. 4[illegible] Arthritis, 1928, Appendix, p. 994.

About four-fifths of these women are engaged in the general nursing of the sick, the source of cases being the general practitioner, the voluntary hospital, and occasionally the medical officer of health. The majority of the cases are medical, many of them chronic ailments, which are extremely exacting. The treatment of diabetes by insulin injections, for example, falls heavily upon district nurses. But Dr. Hogarth states that the number of patients seriously ill, and requiring district nursing, for whom such nursing is not available is small, if, indeed, there are any such cases at all. An analysis of the cases nursed by one local association, employing twenty-five nurses, during a recent month showed that out of the total of 519 the greatest number (158) were cases of measles, and the next (53) post-operative nursing in tonsils and adenoids cases. With the exception of a few bodies attached to religious denominations, all associations have definitely ruled that every case nursed must be under medical supervision. The Queen's Institute allows not more than three observation visits before a doctor is called in.

Few district nursing organizations are concerned with midwifery, which is undertaken by medical practitioners, hospitals, independent midwives, and, in four or five boroughs, municipal midwives; nor do the organizations lay themselves out to undertake maternity nursing, or to staff infant welfare centres, except on emergency or holiday duty. Details are given of the arrangements made for nursing under the former Poor Law authorities, and of the nursing of notifiable diseases under the borough councils. A frequent arrangement under the latter head appears to be the payment of about a shilling for each visit to cases of notifiable disease. All nursing organizations undertake the nursing of infectious cases. Domiciliary nursing of scarlet fever, under special precautions, is carried out in a few boroughs. The average number of visits paid to children suffering from measles is 8.7 per case, and from whooping-cough 11.8 per case. The amount of domiciliary nursing of tuberculous patients is small, because, wherever possible, such patients are offered institutional treatment, for the provision of which the London County Council is responsible. The majority of tuberculous patients in need of nursing treatment at home are in the advanced stages, having returned home to die. School nursing is carried out by a staff of about 360 nurses under the London County Council, but the Council arranges with local district nursing organizations for the services of their nurses in minor ailments and otorrhoea, and between sixty and seventy district nurses are employed in this work. Until institutional provision was made by the Council for the operative treatment of enlarged tonsils and adenoids, the visiting of these cases by district nurses was a heavy task. Rather more than 2 per cent. of the nurses' visits are paid to insured persons under arrangements with the approved society. By no means all societies include nursing among their additional benefits; those which do, make a payment to the nursing association at the rate of 1s. to 1s. 4d. for a first series of visits authorized. Two insurance companies arrange for the nursing of their policyholders, making use of the local associations and the Ranyard nurses.

Dr. Hogarth adds some particulars of the finance of district nursing. The cost per nurse, including all administrative expenditure, works out at approximately £200 a year. Most of the associations have to make tremendous efforts to secure sufficient funds. Patients' payments furnish a rather meagre and uncertain income. It should be made plain that only in exceptional circumstances, as when a doctor makes a very special request for the services of a certain district nurse, does such nurse attend a patient able to pay the usual fee of 5s. a visit for private nursing. Dr. Hogarth concludes with a warm tribute to the amount of individual and collective voluntary effort expended in securing for the poorer classes a nursing service of the highest quality. The service is never denied to anyone who cannot pay for a private nurse. The standard of nursing is at a consistently high level, and the educational value of nursing visits to a home cannot be over-estimated. "The altruistic attitude of the district nurse who remains at the work for any length of time is strikingly apparent. For her the work, distasteful and revolting in some of its aspects, becomes more a vocation than a profession, and for this reason alone it is important that her devotion should not be exploited even in the interests of the general public." An appendix to the survey gives an outline of the schemes of training arranged by the Queen's Institute and by the Ranyard Mission.

MILK-BORNE STREPTOCOCCUS EPIDEMICS

Discussions on the diseases spread by cow's milk often centre round the question whether the cow or the dairy is most to blame. In the case of the two acute streptococcal diseases spread by cow's milk—septic sore throat and scarlet fever—the cow's share of the blame has been unjustly exaggerated in the past; in fact, the cow may now claim to be acquitted of any active share in the dissemination of these diseases. The adjective "active" is used deliberately, because there is no denying that the cow may play a passive part in one of these diseases—namely, scarlet fever. To find this conception of the cow as a passive carrier of scarlet fever streptococcus accepted without demur must have been a source of gratification to Dr. W. G. Savage at the discussion at the Royal Society of Medicine on March 25th, for his ideas on this subject received considerable criticism when first advanced twenty years ago. To-day, however, it seems to be freely admitted by veterinary surgeons that the impetigo-like ulcerations which may occur round the teats of a cow do occasionally become secondarily infected with the haemolytic streptococci of scarlet fever, and so cause the milk to spread the disease. It was most interesting to hear, in the course of last week's discussion, that one veterinary surgeon present had personal experience of the celebrated Hendon outbreak of scarlet fever about forty years ago, when a large herd of cows with ulcerated teats was held to be responsible for the spread of a very serious outbreak of scarlet fever. In regard

to the other type of acute streptococcal infection spread by cow's milk—septic sore throat—it is very regrettable that our knowledge is not more exact. Some excuse may be found in the fact that these epidemics are rarer than they were twenty or thirty years ago ; but when an outbreak does occur, our machinery of investigation has been so slow in moving that the opportunities of tracing the source of the epidemic in its early phases, with all the necessary refinements of bacteriological technique, have not been taken advantage of until too late for any reasonable prospect of success. We shall probably gain a better perspective of the question of the relation of septic sore throats to bovine infections by the type of research recently undertaken by Dr. F. C. Minett and Mr. A. W. Stableforth. One part of this work has been the search for, and study of, haemolytic streptococci in the milk of normal cows, and cows suffering from mastitis, and the comparison of these strains of streptococci with those recovered from human infections. It is surprising to learn how common haemolytic streptococci are in ordinary commercial cow's milk, but comforting to be told also that as far as can be judged by fermentation and agglutination tests these bovine streptococci are distinct from those that endanger human health. In particular, there is no longer any ground for the belief that the streptococci which cause bovine mastitis are pathogenic to man. For several years there has been ample bacteriological and epidemiological evidence to discountenance such a speculation, but the work of Minett and Stableforth has, we hope, settled this once and for all. Discussions such as this often have the effect of raising several new questions for each old one that is answered. In this way they give a direction to future research, and very likely it is this guidance which is their most useful function. Two such questions which were provoked by the discussion in the Section of Comparative Medicine are the necessity of finding some fairly simple test for distinguishing pathogenic from non-pathogenic streptococci, and the desirability of a clearer definition of the disease we call scarlet fever and its relationship to other forms of sore throat unaccompanied by a rash.

THE CAPITAL VALUE OF HOSPITALS

A novel investigation has been made into the capital value of expenditure upon American hospitals.[1] The Committee on the Costs of Medical Care included this inquiry within its programme. The investigation was carried out by Dr. Rufus Rorem, at the cost of the Rockefeller Foundation. The report is most detailed, and, although in its entirety it is only applicable to the hospitals of the United States, it has illuminating references to hospital conditions as we know them at home. There are over 7,000 hospitals with 900,000 beds in the States, and these represent a capital expenditure of over £600,000,000. Of this sum 60 per cent. is represented by hospitals for general, medical, and surgical service. Second in order of total capital investment come the mental hospitals, with 27 per cent. Third come the hospitals for tuberculosis, with about 6 per cent. Special hospitals account for some 2 per cent. Of the general hospitals two-thirds have been provided by "non-profit associations." Of the mental hospitals 90 per cent. are Governmental. In general it is found that cases requiring prolonged custody rather than treatment for acute diseases are dealt with by Governmental institutions. Proprietary hospitals account for some 9 per cent. of the total capital value of hospitals. Endowment capital is not an important factor in the financing of hospital service in the United States. The total number of endowed beds does not exceed 15,000, and of a total of 2,604 non-profit hospitals only 1,060 have any endowment capital. In recent years there has been a great expansion of hospital provision ; one-half of the total number of hospitals appear to have been founded since 1910. The capital expenditure has increased enormously, and it is judged that present-day construction programmes and costs indicate that the expenditure has not reached the end. Much of the new capital expenditure is for intensive development of facilities rather than for the provision of more beds. At the present time there seems to be a slowing down in the founding of new hospitals, the tendency being rather to develop the facilities of existing institutions. It is estimated that in the better class of general hospital each bed represents an investment of from £600 to £3,000. These amounts are irrecoverable. The money for the foundation of these hospitals has not been provided entirely by the generosity of the public, and this is even truer of running costs. The hospitals have assessed fees against certain groups of patients, or for certain types of services, which are considerably greater than the costs of rendering these services. This practice, it is said, is not unlike, in its effect, the sliding scale which seems to characterize the laying down of surgical fees. In this way certain patients have been compelled to make contributions to the charitable services of the hospitals. The justification of the practice is said to lie in the net result, and many hospitals pride themselves on their gains from this practice, which is, in effect, a kind of unofficial taxation. It is noted that in the "voluntary" hospitals of this country much less is ordinarily paid by patients than is paid to the non-profit associations in the United States. The cost of hospital services are considered in relation to other medical services. Loss of employment, physicians' and surgeons' fees, nursing fees, need to be added to hospital bills. Since these are not commonly provided for in the family budget, they are apt to fall with crushing weight. It is because of this circumstance that much outcry is directed against hospital costs, although the amount paid by individuals and the public to hospitals may be less than that for professional services or for drugs. Some of the difficulty is debited to inequalities of professional fees. Because medical men do not receive pay for some cases they charge higher for others. "The payment of physicians for all work done for individual patients or for the public is an important feature of good hospitalization. There is no more reason for the medical profession to render free service in Government hospitals than to assume the burden of expenditure for nurses, orderlies, or supplies. It has often been stated that physicians' personal services do not represent cash outlays for supplies, and hence are not of the same importance economically as other medical expenditures. But such is not the case. The only real distinction is historical, in that physicians in the past have been able to recover the value of their 'donated' services by

[1] [illegible] Hospitals. By C. Rufus Rorem. [illegible] University of Chicago Press. 1931. (Pp. xxii + 231. [illegible] 6s. net.)

assessment against their full-pay patients, whereas nurses, orderlies, and the vendors of supplies have not been able to do so. . . . In the past much medical care would probably have been impossible if physicians had not contributed their services to the care of patients in Government hospitals. But it is undignified for an organized community to ask any group continually to make gifts of services or commodities to the public good without crediting them explicitly with their contributions. This custom must be regarded as a practical makeshift rather than a logical solution of the problem."

A SURVEY OF RELAPSING FEVER

The last monthly epidemiological report of the Health Section of the League of Nations for 1930 contained an interesting account of the distribution and fatality rate of relapsing fever during the past ten years in Europe, Asia, and Northern and Equatorial Africa. Although at the present time there are comparatively few cases in Europe, ten years ago, in the period immediately following the war, there were hundreds of thousands. In the European part of Russia, excluding the Ukraine, for example, the number of cases rose in 1919 to 392,000, and in 1920 to 1,570,000, falling to 965 in 1929. In Poland the epidemic reached its height with the return of refugees who had been driven into Russia during the retreat of the Russian armies in 1915 and 1916. The numbers, which were 3,200 in 1919, rose to 7,200 in 1920, 13,850 in 1921, and 41,200 in 1922. Subsequently, a rapid decline took place, so that only 17 cases were reported in 1930. Severe epidemics also occurred during or after the war in Rumania and Yugoslavia, but no cases were reported in either of those countries in 1930. In Italy, where (like Russia) relapsing fever is endemic, 338 cases were reported in 1925 and 153 in 1929. In Northern Africa the incidence of relapsing fever did not materially alter during the war. Sporadic cases and small circumscribed outbreaks continue to occur in Algeria, Morocco, and Tunis, but Egypt, formerly one of the endemic foci of relapsing fever, has been almost free of the disease since 1926. In striking contrast with the decline of the disease in Europe and North Africa, an extremely extensive and deadly epidemic appeared in Kouroussa in the eastern part of French Guinea, where the disease was endemic, in May, 1921, and spread during the following years throughout Equatorial Africa. In the lake district of the Niger the epidemic wave was particularly high from December, 1921, to the following February. During the first two years the number of fatal cases in the French Sudan and Niger were estimated at from 80,000 to 100,000. In the Chad region it produced the greatest damage in 1926, causing 6,000 deaths in a population of 270,000. In some villages 37 or even 41 per cent. of the population died. Endemic foci of the disease still persist and give rise to epidemic outbreaks in all the savanna region south of the Sahara, where the inhabitants wear clothing and are infested by lice, whereas the naked tribes, especially those of the equatorial forest, escape. In the Asiatic territories of Soviet Russia the incidence of the disease has been similar to that in European Russia. The number of cases, which was 333,666 in 1922, fell to 1,983 in 1929. Relapsing fever has been reported on several occasions in China, but exact statistics are lacking. Since 1852 British India, where the epidemics occur in the hot periods, in association with famine, has been one of the principal foci of relapsing fever. In 1923 28,830 cases, with 7,568 deaths, occurred in the Punjab, and in the United Provinces an epidemic lasted from 1917 to 1920. The fatality rate of relapsing fever varies widely in different countries. As a rule the disease is comparatively mild in Europe or the Mediterranean coast, the mortality ranging from 0.9 to about 5 per cent. In Equatorial Africa and Asia, on the other hand, the fatality rate is much higher. In the French Sudan, for example, it was 17.8 per cent. from May, 1921, to March, 1923; in the Upper Volta territory, from 1921 to 1928, 25.5 per cent.; and in the Punjab, during the 1923 epidemic, 26.2 per cent. The higher fatality of the disease in Africa is probably to be attributed to a number of factors, which include a greater virulence of the causal spirochaetes, a greater degree of louse infestation, and impaired resistance of the population.

MENTAL AFTER-CARE ASSOCIATION

The annual meeting of the Mental After-Care Association was held at the Haberdashers' Hall on March 25th, under the chairmanship of Lord Wakefield of Hythe, when the report and accounts for the year were presented, and Dr. Reginald Worth was elected chairman of the council in place of Sir Maurice Craig, who, to the regret of all concerned, has had to relinquish his office owing to ill-health. Lord Wakefield said that there was every reason to hope that people generally were now regarding the whole subject of mental illness with a new sympathy and understanding. The activities of the association were increasing to such an extent that its title had almost ceased to be properly descriptive of the work, which was now, to some extent, preventive. At whatever stage the help of the association was offered, its friends rejoiced at its growing opportunities for service. Dr. Worth, after remarking that this was the first occasion on which the superintendent of a large mental hospital had been elected to the position of chairman, said that the council desired to widen its field of operation, and to that end was in communication with public assistance committees and medical superintendents throughout the country, offering help in respect to early treatment and after-care. It was now co-operating with more than a hundred mental hospitals. The Mental Treatment Act had increased the association's work, and it was hoped, with the help of grants from the public authorities, to be able to deal with the cases coming under that Act. The number of patients for early treatment who had been referred from general hospitals with psychiatric out-patient departments was 410, and practically all of these had so far recovered as to be able to return to their homes and occupations without requiring institutional treatment. The number given compared with 161 in the previous year. Sir Hubert Bond said that he wondered whether it was fully realized even yet what the Mental Treatment Act could do if properly used. In the enfranchisement of the treatment of mental illness the Act bore the same relation as Magna Charta bore to the liberties of the people. It did not need much imagination to see that if full effect were given to Section 6 (3), the Act might have a powerful influence ultimately upon

the destinies of the association. He said "ultimately," because it was extraordinary how slowly came the realization of the value of something which was right to one's hand. In France a hundred years ago an after-care society was formed, and the present association in Britain had been in existence for more than fifty years, yet it was only to-day that the local authorities could legally themselves provide after-care or subsidize a voluntary body to do it for them. The council was enlarging its activities, not by merely increasing the number of outposts, but by widening the nature of its work, and he believed that the title of the association would soon have to be altered. If it were known as "The After-Care and Mental Health Association" this would in part restore the name by which the association was originally known, and would suggest in fitting and concise terms both its primary and its wider aim. Dr. Walter Carr referred to the great change which had taken place in the general attitude towards mental illness. It was not so very many years ago that mental patients were regarded as the victims of demoniacal possession, and the padded room and the strait jacket had only lately gone out of use. But one blot had remained upon mental hospital administration in that, officially, until the Mental Treatment Act, no provision had been made for the after-care of these unfortunate persons when they had been restored to reason. In a mental hospital patients were shielded as far as possible from the strains and stresses which had probably brought about their condition, but when they returned home to a family who viewed them with apprehension, and found their occupation gone, the probability of a relapse sooner or later was very great. It was to forestall this that the Mental After-Care Association existed, but the prevention of the original attack, not merely a relapse, would be increasingly important in the work of the society. This was work best done under voluntary auspices, removed absolutely from officialism.

QUININE PRODUCTION IN INDIA

Sir Charles MacWatt, late Director-General of the Indian Medical Service, read an interesting paper at the Cinchona Tercentenary Celebrations last December, in which he pointed out that the production of quinine in India was inadequate to supply the amount she actually used, and that this latter amount was only a small fraction of that needed to have any effect on the malaria problem. India produces about 40,000 lb. of quinine a year; she consumes 160,000 lb., and Sir Patrick Hehir estimated that the minimal amount needed to produce effect was 970,000 lb. Dr. K. S. Ray[1] in a recent article explains the situation more fully. The use of quinine per head of the population per annum is in Italy 16 grains, in Greece 24 grains, whereas in India it is 3½ grains, and in the most malarial districts of Bengal little more than 1 grain. The world price of quinine is fixed by the Amsterdam Bureau, and the Indian Government fixes its price at practically the same level. As a result the drug is too expensive for the population to buy, surplus stocks accumulate, and malaria flourishes. The number of cases of malaria treated in the hospitals and dispensaries in the British Provinces is just over 8 million a year. The article concludes with an appeal to the Indian Government to alter its quinine policy completely, and to aim at supplying the needs of the country for this essential drug and to make every effort to lower its price to a level that will render it available for the poorest sections of the population, who stand most in need of the drug.

[1] Ray, K. S., *Indian Medical World*, January, 1931, 465.

NATIONAL BABY WEEK COUNCIL

The first National Baby Week was held fourteen years ago, and at the annual general meeting of the council of this organization, on March 25th, a gratifying record of progress was announced. During the past year special efforts were made to impress upon the public the need for a national maternity service scheme, for better provision of nursery schools, and for inspiring among the classes of the population not at present being reached by statutory and voluntary welfare schemes the desire for a better knowledge of parentcraft. These topics were promulgated by health weeks, and through the press; literature was distributed to church and other congregations; film displays were given, and posters exhibited. Three new cinematograph films were added to the council's list in 1930, depicting respectively life at a nursery school, a father's interest in an infant welfare centre, and the change brought about in a squalid and unhealthy home by the visits of a health visitor. The council has now eleven films available for propaganda purposes. A lantern lecture on rickets and other common nutritional diseases was published in 1929, and has proved very useful to medical lecturers on the subject; the set contains in all nearly one hundred slides, and selections can be made from it for special purposes. The council has now six correspondents in India, five in Australia, four in Canada, two in South Africa, and one each in Malaya, Kenya, Tanganyika, Bermuda, New Zealand, Ceylon, and West Africa. In this way there is arranged a free interchange of practical information about the various aspects of infant welfare, and the steps that are being taken in different places. A donation of £1,000 from Dr. A. Wander enabled the council to augment its supply of cinematograph films and posters, and to intensify the work in other directions also. At a meeting of the council last November a discussion on the physical health of the child between the ages of 1 and 5 was opened by Drs. Eric Pritchard, D. H. Geffen, and Sophia Friel, and the interest then aroused led to its continuance by special request at last week's meeting. The point chiefly emphasized was the necessity for routine medical examination of children between these ages.

At the meeting of the Royal College of Physicians of London held on March 30th, Lord Dawson of Penn was elected President, in succession to Sir John Rose Bradford, Bt.

The annual meeting of the Canadian Medical Association will be held this year at Vancouver from June 22nd to 26th.

Members of the medical profession will share the regret widely felt at the death, on March 29th, of Miss Margaret McMillan, upon whom the Companionship of Honour was conferred last year for her pioneer work in founding school clinics and nursery schools.

TOXIC JAUNDICE

LUMLEIAN LECTURES BY SIR WILLIAM WILLCOX

(*Concluded from page 553*)

In his second Lumleian Lecture Sir WILLIAM WILLCOX gave a description of the symptoms of toxic jaundice, grouping them under two headings: symptoms of the causal agent, and symptoms due to the effect on the liver of the toxic cause. The first group was naturally of great variety. In acute phosphorus poisoning, for example, there was a burning sensation in the mouth and throat, accompanied by the symptoms of acute gastro-enteritis. In tetrachlorethane industrial poisoning an intervening period of general malaise and toxic gastritis of days or weeks might precede the onset of jaundice and hepatic symptoms. The jaundice following quinoline derivatives, such as atophan, might be preceded by no premonitory symptoms, or only by slight nausea or occasional vomiting. The symptoms due to the effect on the liver of the toxic cause varied in intensity according to the amount of impairment of function of the liver cells.

ACUTE NECROSIS OF THE LIVER (ACUTE YELLOW ATROPHY)

The lecturer found fault with the term "acute yellow atrophy," pointing out that it was necrosis, not atrophy, which was the pathological change, that the liver might in acute cases be larger than normal, and that its colour, though generally yellow, was reddish in some of the more prolonged cases. He preferred the term "necrosis of the liver" to "yellow atrophy." This condition had been classed as a special disease affecting the liver, but pathological study of recent years had shown that it was really a condition resulting from the action of some profound toxic cause, due to an exogenous chemical poisoning, to toxins of some infection of biological origin, or to the poisons of the auto-intoxication of a disordered metabolism. It had become more frequent in occurrence during recent years, owing to the increased exposure of individuals to the action of toxic drugs having a selective effect on the liver, such, for example, as the arsenobenzol derivatives in the treatment of syphilis and the quinophan group of drugs in the treatment of chronic rheumatism.

The symptoms of necrosis of the liver were dramatic in type, and ran a characteristic and usually a rapidly fatal course. They were ushered in by nausea, vomiting, and gastric irritation; the tongue was furred, dry, and tremulous; there was a feeling of mental anxiety and impending disaster; and the patient was difficult to manage. Headache and photophobia were sometimes present. These and other premonitory symptoms might last from a few hours to a few days, and were then commonly succeeded by delirium, drowsiness, and stupor, passing into coma, during which convulsions might occur. Death took place at varying intervals, usually three or four days after the onset of the symptoms of acute necrosis.

TREATMENT OF TOXIC JAUNDICE

Treatment during the stage when the jaundice was latent must take the form of the immediate removal of the toxic cause. He had emphasized in a paper published in the *British Medical Journal* in 1916 the importance of the free administration of alkalis. Saline aperients such as magnesium and sodium sulphate were of value in promoting emptying of the gall-bladder. Glucose should be given freely. He had used liver extract in several cases of toxic jaundice, and it appeared to be of benefit. Diet should be arranged so that as little burden was thrown on the liver cells as possible. Protein should be greatly reduced, and fatty foods eliminated. When the grave symptoms of acute necrosis were commencing, active treatment should be adopted without delay. Glucose in 5 or 10 per cent. solution in normal saline should be given subcutaneously or intravenously. Alkalis such as sodium citrate and sodium bicarbonate should be given by the mouth, and sodium bicarbonate and glucose by rectum. If haemorrhages commenced 1 per cent. calcium chloride might be given intramuscularly or intravenously in one dose of 10 to 20 c.cm., and at the same time parathormone in a dose of 10 units subcutaneously. If coma developed it might be advisable to perform lumbar puncture and draw off 10 to 20 c.cm. of the cerebro-spinal fluid.

CLASSIFICATION OF TOXIC CAUSES

Sir William Willcox classified the causation of toxic jaundice into (1) chemical poisons, (2) bacterial poisons, (3) protozoal poisons, and (4) auto-intoxications. He dealt first with the halogen group of organic compounds, mentioning that his interest in this group of poisons was stimulated by an investigation which he had carried out on behalf of the Home Office twenty-two years ago on a case of fatal inhalation of carbon tetrachloride vapour by a young lady who died of heart failure during the process of having her hair shampooed with this substance, which, weight for weight, was four times as toxic as chloroform. He related some unusual cases of toxic jaundice following chloroform and also following tetrachlorethane.

Avertin, which had recently been introduced as an anaesthetic, had undoubtedly a marked toxic action on the liver, and although no cases of toxic jaundice had yet been recorded so far as he knew, yet the possibility of danger must be borne in mind. He related an experiment on a rabbit performed by Dr. F. B. Parsons, and after a personal examination of the sections he thought it must be taken as proved that avertin, like the other halogen organic compounds, was a liver poison, and must be used with care. Overdosage and repeated administration would increase the risk of liver damage and toxic jaundice. The occurrence of toxic jaundice after the administration of arsenobenzol derivatives was now well recognized. The patient could be protected by the taking of glucose before the doses were given.

QUINOLINE DERIVATIVES

The lecturer referred also at some length to the quinoline derivatives, which were known under various trade names. In the *British Medical Journal* in 1926 he and others had drawn attention to the numerous cases of toxic jaundice, some of them fatal, which had resulted from the use of this group of drugs. The liability was now generally recognized in this country, and the observations had been confirmed by similar experiences in America. In the *Mayo Clinic Staff Meeting Reports* (May, 1930), a fatal case of toxic jaundice following the administration of a cinchophen derivative was recorded. The jaundice following the taking of quinophan was deep, and lasted for several weeks. For some days it was obstructive in type. The gall-bladder was not enlarged, the obstruction being intrahepatic, and due to the hepatitis caused by the drug. He cited one recovered and one fatal case of atophan poisoning.

A preparation on the market known as gorum cachets contained an appreciable amount of atophan, and two cases of toxic jaundice following the taking of these cachets had recently come under his care.

One of these was a woman, aged 70, who developed quickly deepening toxic jaundice about three weeks after a course of gorum cachets (two daily for six days). Ascites appeared, followed by severe haematemesis, and death took

place two months after the onset of the condition. There was no history of alcoholism in the case. The hepatic cirrhosis was no doubt the result of the hepatitis following the quinophan in the gorum cachets.

The lecturer described two very prolonged cases of poisoning from trinitrotoluene, and instanced a number of other aromatic organic compounds which had given rise to symptoms.

ALCOHOL AND CIRRHOSIS OF THE LIVER

It was universally agreed that the action of alcohol in large doses caused fatty degeneration of the liver cells. In some cases the enlargement of the liver was great, and the organ of a pronounced yellow colour, the appearance resembling that seen in fatal cases of acidosis, or delayed chloroform poisoning in children. In this type of case vomiting might be a very prominent feature, so much so as to give rise to the suspicion of irritant poisoning; and he quoted an interesting case of this type which he had investigated on behalf of the Home Office, and in which his investigation had incidentally dispelled certain suspicions of arsenical poisoning. In a few cases acute alcoholic excess had given rise to acute necrosis of the liver, with its accompanying group of fatal symptoms. It was clear that in most cases of hepatic cirrhosis alcohol played a predisposing part, permitting the passage of toxins of bacterial origin through the gastro-intestinal mucous membrane, and so on to the liver. It was these toxins, not the alcohol, which caused the progressive hepatic fibrosis. It must also be borne in mind that cirrhosis of the liver not infrequently occurred in persons who had never taken alcohol. There were many chemical agents other than alcohol which would cause cirrhosis, and also many infective causes, such as chronic intestinal infection. That being so, it could not be too strongly emphasized that, where death was due to cirrhosis of the liver, the cause of death should be regarded as "natural" unless the contrary was proved.

"The custom of holding an inquest as a matter of routine in cases of cirrhosis of the liver is, in my opinion, contrary to the most modern views of pathological knowledge regarding the cause of this condition, and it is a custom which should be discontinued. Needless publicity of a character most painful to the relatives of the deceased is thereby caused to no purpose."

The lecturer went on to admit, however, that occasionally a rapidly acute cirrhosis of the liver of virulent type might be set up by alcoholic drinks. Several such cases had been recently reported where death had resulted from what must be regarded as alcoholic poisoning. The drink in question was known as "Lisbon wine"—in the South and East of London as "Red Lizzie"—and caused a very acute alcoholic intoxication. It resembled port wine in colour, though not in taste. He gave details of one case of this kind recently under his care at St. Mary's Hospital, and said that it was one of acute cirrhosis of the liver caused by the consumption of a very toxic form of alcoholic drink, which was taken right up to the time of the onset of the symptoms. This was an example of the type of case of cirrhosis which should be reported to the coroner, and for which a death certificate should not be given. In his opinion the decision as to whether a fatal case of cirrhosis of the liver should be regarded as due to natural causes or as the direct result of alcoholic poisoning could only be made by the medical practitioner in charge of the case, and he would be wise, if necessary, to obtain expert advice on the point.

Touching on certain other poisons, the lecturer said that lead poisoning as ordinarily occurring from industrial or accidental causes was not definitely associated with toxic jaundice, but the intravenous use of lead preparations in the treatment of cancer had shown that toxic jaundice was a danger to be looked for and guarded against. Poisonous fungi eaten in mistake for edible mushrooms produced acute gastro-intestinal irritation and intense degeneration of the liver cells, with marked fatty change in them. Again, the venom of snakes of the viper order caused a very marked local extravasation of blood, which might involve a large area around the bite, and local and sometimes general jaundice might occur after the bite of such snakes. Finally, the lecturer mentioned that attention had lately been called to the occurrence of toxic jaundice after the administration of *acriflavine*.

JAUNDICE DUE TO TOXINS OF BIOLOGICAL ORIGIN

In his third and concluding lecture Sir William Willcox considered the varieties of toxic jaundice due to toxins of biological origin—namely, bacterial, protozoal, and auto-intoxications. He pointed out that the bacterial infection might be that of a micro-organism the characters of which were generally accepted as specific, or it might proceed from one of a group of organisms, such as the streptococcal group, the specificity of which was indefinite.

Jaundice was well recognized as a complication of typhoid fever. Often the cause appeared to be an ascending infection resulting in catarrhal inflammation of the intrahepatic bile ducts. Paratyphoid fevers A and B were extremely common during the Dardanelles and Mesopotamian campaigns. In enteric and paratyphoid fever the commonest time of onset of jaundice was towards the second week. He had seen cases, however, in which jaundice occurred within the first six days, and in a few it was present at the onset of the symptoms. Toxic jaundice had been observed by him in one case during the severe febrile reaction, lasting several days, which followed a full dose of prophylactic typhoid vaccine.

Speaking of parenteric infections, the lecturer said that the group of coliform bacilli concerned might give rise to an acute illness closely resembling typhoid fever clinically, and this group of organisms was often associated with abdominal symptoms of a chronic or subacute type, such as jaundice, cholecystitis, and enteritis. In some cases of chronic toxic jaundice of intestinal origin *B. coli communis* might play a causative part. Food-poisoning organisms were closely allied morphologically to the parenteric group of organisms, though clinically they were entirely different, for they gave rise to acute enteritis. Food-poisoning infections were not infrequently associated with toxic jaundice; he described a typical case.

The occurrence of jaundice in influenza, especially of the gastro-intestinal type, had long been recognized. Epidemics varied greatly as regards the occurrence of jaundice; in some it might be relatively common, while usually it was absent or very rare. Jaundice occurred with irregularity in outbreaks of pneumonia; usually it was a rare symptom. Toxic jaundice had been observed on many occasions during the acute streptococcal infection associated with tonsillitis or with sinus inflammation in the nasopharynx. In acute streptococcal septicaemia, toxic jaundice sometimes occurred owing to the action of the circulating toxins in the liver cells. Staphylococcus infections, if of an acute or subacute type, had been associated with the occurrence of toxic jaundice, and several cases might be quoted.

EPIDEMIC CATARRHAL JAUNDICE

This disease occurred with great frequency during the various war campaigns, and an account of its incidence in the Dardanelles was published by the lecturer in the *British Medical Journal* in February, 1916. An interesting account of a recent epidemic occurring in

Yorkshire was published by Dr. Pickles in the *Journal* of May 24th, 1930. Epidemic catarrhal jaundice was ot a new disease, and very many cases were recorded the American and South African wars. Up to the present it had not been possible to identify any specific organism. Like typhoid, the disease did not appear to be contagious from person to person, though many people might become infected from a common cause. He described the symptoms, and said that it was important to realize that sometimes in catarrhal jaundice the pyrexial period might be prolonged; he had seen it last or fourteen days. The jaundice might persist for several eeks, even as long as ten, ultimately clearing up. Unless this was realized, there was risk of an unnecessary surgical operation on the assumption that obstruction of the common bile duct existed. A curious and constant feature of catarrhal jaundice was the definite increase in the deep cardiac dullness in the fourth intercostal space to the right of the sternum. Usually cases of catarrhal aundice gave rise to no anxiety, but a cautious prognosis hould be given, since it was known that fatal symptoms of hypohepatism due to necrosis of the liver occurred in from 0.5 to 1 per cent. of cases. The symptoms of this grave condition were seen usually about ten days after the appearance of the jaundice, but in one case they occurred on the second day. Some cases, at the time of the onset of the symptoms of hepatic failure, were not deeply jaundiced, and there appeared to be no relation between the depth of the jaundice and the frequency of hypohepatism and necrosis. From a study of the clinical symptoms and post-mortem findings it appeared that in he majority of cases of epidemic catarrhal jaundice there was an ascending catarrh of the bile ducts leading to a temporary obstruction, which was generally interhepatic. In the more serious cases there was in addition a marked degeneration of the hepatic cells, which in the fatal cases went on to complete necrosis.

PROTOZOAL POISONS AND AUTO-INTOXICATIONS

The occurrence of jaundice in syphilis was too well known to need mention. Relapsing fever was frequently associated with jaundice. In yellow fever marked cellular necrosis occurred in the liver, with which jaundice was often associated. The marked action of the malarial parasite on the red blood corpuscles led to hepatic and splenic enlargement and anaemia, and the hepatitis resulting from a malarial infection was often associated with aundice, especially when the infection was of the malignant type. In a malarial patient jaundice was much more likely to occur when marked anaemia was also resent. Blackwater fever was commonly associated th early jaundice of the toxic type. Icterus was a rare complication of typhus fever, and was seen by him in only two out of several hundred cases in Mesopotamia. As a result of hepatitis and blood destruction in kalazar it was a fairly common symptom.

The toxaemias of pregnancy were manifestations of grave toxaemias of autogenous origin, in which intense fatty degeneration and necrosis of the liver were not uncommon, and symptoms of acute hypohepatism, often associated with jaundice, were not infrequent complications. In recurrent vomiting (acidosis) in children, when death occurred, post-mortem examination usually revealed a large yellow liver showing intense fatty degeneration and necrosis of the hepatic cells. He did not believe that the fatty degeneration was the result of the acidosis; the true explanation was to be found in the presence of some underlying toxic cause, such as infected tonsils or adenoids, intestinal toxaemia, or grave errors in diet, whereby liver degeneration was set up.

CONTROL OF DRUGS: A WARNING

In concluding his lectures Sir William Willcox said that the great variety of drugs in common use which might act as liver poisons and produce dangerous toxic jaundice showed how necessary it was that, before they were placed on the market, these drugs should be submitted to careful toxicological and therapeutic tests on the human subject as well as on animals. The medical profession should be fully informed, not only of the therapeutic properties of new drugs, but also of the dangers which might arise from idiosyncrasy or overdosage. At present doctors were insufficiently informed of the dangers resulting from the new drugs introduced into this country in increasing amount. The present system of scheduling poisons was quite inadequate to keep pace with the rapid developments of the chemical manufacturing industries, which were daily launching new and imperfectly tried complex organic drugs on the market. Drugs of the quinophan group were not even on the Poisons Schedule; they could be sold by any unqualified person, and purchased at will by the public without medical intervention or advice. The system of the control and sale of drugs possessing powerful toxic properties was most imperfect and unsatisfactory, exposing the people of this country to great danger from the taking of new drugs advertised as possessing wonderful curative properties, without any mention of their toxic effects. The Pharmacy and Poisons Bill at present before Parliament proposed to place the control and sale of poisons under the supervision of an advisory committee, to be called the Poisons Board, on which the medical profession would have, he hoped, an adequate representation.

SICK AND WOUNDED IN WARFARE

NEW INTERNATIONAL CONVENTION

From start to finish of the great war the protection afforded to medical personnel and units, and also the methods of dealing with captured material and convoys associated with or belonging to the medical organization of an army, were governed by the Geneva Convention of July 6th, 1906. Sick and wounded captured by the enemy were prisoners of war, and, as such, their treatment by the captor State was regulated in accordance with the Annexe to the Hague Convention of October 18th, 1907, concerning the Laws and Customs of War on Land. In view of the wide experience gained in these matters by every nation involved in the great war, and the suffering and anxiety affecting almost every household among the combatant powers, it was impossible for these Conventions to remain standard for all time. The plenipotentiaries at Geneva, animated by the desire both to lessen the evils inseparable from war and to alleviate the condition of prisoners of war, have signed two new Conventions: "International Convention for the Amelioration of the Condition of the Wounded and Sick in Armies in the Field,"[1] and "International Convention relative to the Treatment of Prisoners of War."[2] Both are dated Geneva, July 27th, 1929, and have been presented to Parliament by the Secretary of State for Foreign Affairs.

Of the two, the former is perhaps the more interesting to our readers. As was to be expected, provision has been made for the conditions of modern warfare, although many of the Articles of the Geneva Convention of 1906 remain substantially the same. They are now presented in Articles has been improved. They are now presented in a more logical manner, which makes their contents more

[1] Cmd. 3793. London: H.M. Stationery Office 1931 (6d. net.)
[2] Cmd. 3794. London: H.M. Stationery Office 1931 (1s. 3d net.)

easily followed and remembered. Points regarding the protection and return of captured personnel, both regular and auxiliary, employed in medical units, medical equipment, and transport, and the use of the distinctive emblem in peace and war, are now more clearly defined. This should lead to fewer misunderstandings. Some of the Articles will tend to ease anxiety and bring comfort to the relatives of the fallen, because greater attention is to be paid to the recording of deaths, the burial or cremation of the dead, the marking of graves, and the organization at the commencement of hostilities of a Graves Registration Service.

COLLECTION OF WOUNDED AND PROTECTION OF MEDICAL UNITS

The two Articles which are perhaps the most important from the point of view of the medical services are those designed to facilitate the collection of wounded by the arrangement of local armistices, and to give protection to medical units by a distinctive marking which will make them easily distinguishable by land, air, or naval forces. The first of these will appeal to medical officers engaged in the task of clearing wounded from the field of battle, and many will hope that in time of war the respective commanders of the combatant forces will find opportunities for putting it into practice. Such a procedure may, however, only be possible in small wars between civilized powers, when chivalry finds an outlet in manœuvre and minor actions, and is not dulled by the slaughter which results from concentration of troops and guns, as in France and Flanders. It was possible in the early days of several campaigns during the late war, but it is difficult to imagine local armistices being feasible in a world war, with battles raging for weeks and months, instead of days, along an iron front extending over continents.

With regard to the protection of medical units, it is generally possible to carry this into effect in back areas and in open country, especially during warfare conducted by small expeditionary forces. It is not so easily accomplished in battle areas where troops, batteries, and military stores are concentrated, as they were on the Western Front. Here the distinguishing mark might only attract undesired attention to the military formations in the neighbourhood. Again, though ideal in theory, it is not always possible in practice to confine the evacuation of sick and wounded casualties to specially marked Red Cross ambulance transport. The exigencies of the moment may demand the use of ordinary motor vehicles, trains, ships, and transports. If these should be damaged by enemy action while carrying sick and wounded, there can be no redress: it is but the fortune of war.

It is only natural to find that in the new Convention consideration is now given to aircraft as a means of ambulance transport. They are to be painted white and bear the emblem of the Convention, in addition to their own national emblem. The Red Crescent and the Red Lion and Sun on a white ground will be recognized in the case of countries using these emblems instead of the Red Cross. There are certain necessary restrictions attached to the use of medical aircraft. In the absence of special and express permission, flying over the firing line and over the zone in front of clearing stations and dressing stations, and generally over all enemy territory, is prohibited. Medical aircraft flying over enemy areas must obey every summons to land.

Finally, two important points regarding the application and carrying out of the Convention are made clearer. The Geneva Convention of 1906 was binding only if all the belligerents were parties to it. The provisions of the 1929 Convention are to be respected by the contracting parties in all circumstances. If one of the belligerents is not a contracting party, the Convention is to remain in force between those belligerents who are contracting parties. Should non-observance of the Convention be reported the aggrieved party may demand an inquiry. If the claim is sustained, the defaulting belligerent shall put an end to and redress the wrong as promptly as possible.

PRISONERS OF WAR

The Convention dealing with the treatment of prisoners of war, among whom are included sick and wounded other than medical personnel, may possibly remind medical officers of their own regulations regarding arrangements for troops in billets and depots. The present Articles are idealistic; if they can be carried out in the spirit in which they are written the lot of prisoners of war should be by no means unhappy. When nations are involved in intense warfare, however, it will not be an easy matter to put the provisions into practice. Prisoners are to be evacuated from the front or battle area as quickly as possible, except those who by reason of their wounds or maladies run greater risks by being evacuated. They are not to be employed on work connected with operations, or on unhealthy or dangerous work. They are not to suffer corporal punishment, or be confined in dark, insanitary cells. Improvements are recommended in the social amenities which they may be permitted to enjoy, greater facilities being afforded in such matters as recreation, sport, the writing of letters, and the receipt of letters and parcels. Canteens are to be established, and greater attention is to be paid to the financial transactions of captured personnel.

Of chief importance to medical officers and the medical profession as a whole are the Articles dealing with hygiene, preventive medicine, and treatment. Prisoners are not to be detained in bad climates. As far as possible, different nationalities are to be segregated. Special attention is to be paid to hygiene, food and clothing, medical inspection, and treatment. In short, there is little difference between the detail of this Convention and the regulations in force for troops serving at home or abroad in peace or in war. Whatever may transpire should these Articles be put to the test, it is almost safe to prophesy that modern civilized powers will, from the purely materialistic point of view, take every precaution to prevent the spread of disease from prisoners to their own combatants or services. This will ensure for prisoners of war careful medical inspection and treatment.

Two Articles in this Convention will appeal alike to friend and foe, active combatant, and neutral. One lays down that "belligerents shall be required to send back to their own country without regard to rank or numbers, after rendering them in a fit condition for transport, prisoners of war who are seriously ill or seriously wounded." Guiding principles are given to show the disabilities or diseases which bring prisoners of war under this category. The other deals with the appointment of mixed medical commissions to examine such sick and wounded prisoners and make the proper decision with regard to them.

Among the concluding Articles is a recommendation that belligerents shall establish information bureaux at the outset of hostilities, in order to supply particulars about prisoners of war in their territory, and that a central agency shall be set up in a neutral country for the purpose of distributing this information. This recommendation cannot be over-emphasized, for many will still recall the anxious scanning of casualty lists during the great war, the daily visits to war departments, and the weary waiting in suspense for news of friend or close relation reported as "missing" or "prisoner of war." Whatever war entails for the armies engaged, the anxiety and suffering of those at home should not be increased by withholding personal information about their nearest and dearest.

THE LONDON HOSPITAL SERVICES

The Wellcome Historical Medical Museum opened its hospitable doors on the evening of March 26th for a reception to representatives of London hospitals, both voluntary and municipal. Those present included hospital secretaries, members of the Central Public Health Committee of the London County Council, and of the Consultative Committee of representatives of the voluntary hospitals, officers of the King Edward's Hospital Fund for London, and representatives of the British Hospitals Association. The gathering was presided over by Lord BURNHAM, chairman of the Propaganda Committee of the King's Fund, who said that the idea behind the conversazione was to form as far as possible a common bond between those who were responsible for the voluntary hospitals of London on the one hand, and, on the other, those who were now charged with the task of administering the great body of public institutions which had until lately been under various authorities, but the control of which had now been unified, greatly to the public advantage, under the London County Council.

THE FUTURE OF VOLUNTARYISM

Lord MACMILLAN then delivered a brief address, pointing out that there were probably few great branches of public service in which there was less of the spirit of controversy than in the hospital service. The very nature of its activities made controversy unseemly. But a most interesting problem of the moment in the hospital world was presented by the new responsibilities and powers conferred upon local authorities by recent legislation. There had always existed the voluntary hospitals on the one hand and the rate-provided infirmaries on the other, which had shared between them the provision of medical treatment for the sick poor, and both had played their part in the life of the community without any serious conflict or overlapping. Now that the administration of the old Poor Law hospitals had passed into the capable hands of the principal local authorities, with new powers and new ideals, some apprehension had arisen as to the relation in future of their activities to the voluntary hospital system, but personally he was confident that the change was in the public interest, and also in the interest of the voluntary hospitals themselves. The most difficult questions, in domestic as in international affairs, arose over frontiers, and the problem was how to adjust the spheres of activity of the voluntary hospitals and the council hospitals so that each might render the best service of which it was capable. Some people had been foolish enough to say that the passing of the Local Government Act, 1929, sounded the knell of the voluntary system. Lord Macmillan did not believe this for a moment, nor was it the view of those responsible either for the passing or for the administration of that measure. Moreover, the London County Council was far too wise a body not to recognize what a vast asset the voluntary hospitals represented for the community which it governed, and what a burden would be placed upon the Council were it to attempt to supersede them. Human nature, too, was equally on the side of the voluntary hospitals. The relief of suffering had always called forth the sympathies and the help of the voluntary worker, and the magnificent institutions which had been derived from voluntary effort were the best testimony to that abiding human instinct. Fortunately, Parliament had provided the means for co-operation by making provision for consultation between local authorities and the voluntary hospitals, and already there was in existence a consultative body representative of the voluntary hospitals which was in active contact with the Central Public Health Committee of the London County Council. With such a spirit animating both parties, nothing but good could result. The British were a wonderful people for compromises, and in this sphere he had no doubt they would be as successful as in other spheres of public life. Lord Macmillan concluded by expressing his amazement at the way in which, in a time of high taxation and financial depression, the voluntary hospitals had managed to prosper. Taking the balance sheets of the London voluntary hospitals, there was actually, over a period of five years, a credit margin; he only wished that the national finances had been conducted with the same success.

Sir GEORGE HUME, a member of the London County Council, gave some idea of the programme of the Council in regard to the health services hitherto controlled by the Metropolitan Asylums Board and the boards of guardians. These particulars have already appeared in the *Journal*. He strongly denied that there was any feeling on the part of the Council that, having so large a share of the hospital accommodation under its control, it would be desirable, from the point of view of uniformity, to include the voluntary hospitals under the same control. The London County Council was as keen as any other body that the voluntary system should be maintained and encouraged. It had also interpreted very broadly the requirement for statutory consultation, and had taken the Voluntary Hospitals Committee into its counsels on proposals for uniform scales of salary and conditions of service for the medical and other staff, questions of medical education, particularly instruction in obstetrics, and other matters. One striking example as showing the attitude of the Council to the voluntary hospitals was furnished by the big estate at Becontree, which had now a huge population. Instead of establishing a municipal hospital there, the King George Hospital had been established in Becontree, encouraged by the Council, and was worked on voluntary lines, with splendid assistance from the King Edward's Hospital Fund.

England and Wales

Extensions at Nottingham General Hospital

A new operating theatre and children's ward at the Nottingham General Hospital were opened on March 25th by Lord Moynihan, P.R.C.S. The theatre, which cost £7,000, has been presented to the hospital by Sir Louis Pearson, and the children's ward, accommodating twenty-seven patients, by Mr. W. G. Player. Lord Moynihan, at the opening ceremony, after a reference to his own happy associations with Nottingham during the war, when he was consulting surgeon to the Northern Command, reaffirmed his faith in the voluntary hospital system. It was said to be moribund and effete, but, in fact, the voluntary hospitals of the country were adding rather more than 1,000 beds every year to their previous accommodation, and were rather more than paying their way. At the end of each of the last four years the income of the provincial hospitals had been £1,000,000 or more in excess of the previous year's income. Certainly one party in the State was prepared to have the hospitals of the country under State control, but if that were brought about it would mean that the hospitals came under an authority which would impose laws without the possibility of understanding the work as did those who had spent their lives in voluntary hospital service. The voluntary hospitals represented a peculiarly English way of doing things, quietly and undemonstratively, but with a higher degree of efficiency than attached to any system in any other country in the world. Lord Moynihan said how much he would like to see Nottingham with a medical school; it had abundance of material, and the profession in Nottingham included many who were admirably qualified to serve as teachers. He also declared that in no other town he had visited in connexion with hospital work had he been so greatly impressed as at Nottingham by the comradeship between the lay and the medical workers. Mr. R. G. Hogarth, a former President of the British Medical Association, in speaking to a vote of thanks, said how greatly complimented he was that

one of the wards of the general hospital should bear his name in consideration of his association with the hospital over a long span of very happy years.

"Nerves" and the Public Health

Professor Major Greenwood, F.R.S., delivered a Chadwick Public Lecture, entitled "'Nerves' and the public health," in the Hall of the British Medical Association on March 26th, with Sir James Purves-Stewart in the chair. Professor Greenwood said that although most people thought they knew what it was to suffer from "nerves," a generally acceptable definition of those troubles of the emotions which the older writers called the effects of the soul was hard to find, almost as hard as to explain what business a medical statistician had to meddle with such abstruse questions. The medical statistician did not seek out these things; they obtruded themselves upon his notice. In a succession of inquiries with which he had had to deal as a statistician, ranging from industrial accidents to telegraphist's cramp, the psychological side of the problem had persisted in forcing itself upon his attention. The stages of the research made by the investigators of the Industrial Health Research Board into the causation of industrial accidents were described, and it was shown that the results of psychological tests employed by the investigators were correlated with the accident liability of the testees. Those who did well at these tests had 23 per cent. fewer, and those who did badly 25 per cent. more, accidents than the average. Professor Greenwood then showed that a serious proportion of lost time due to sickness, and an enormous proportion of long sick leave in industry, were attributable to psychoneurotic illness. He described the methods of investigation used by the Industrial Health Research Board, involving the co-operation of a statistician, an experimental psychologist, and a physician, which has been explained in detail in a recent report (No. 61). Professor Greenwood further pointed out that the validity of the inferences drawn by the investigators was capable of statistical control in various ways. He commented on the factors of modern life, which tend to accentuate the importance of "nerves," and argued that only by a combination of clinical and experimental methods of diagnosis was it possible to reach clear knowledge of the facts. He called attention to the steps which had been taken within the University of London—notably the establishment of a chair of medical psychology at the London School of Hygiene and Tropical Medicine—to make it possible for medical men to acquire a training in these methods. In conclusion he said:

> "I believe that teaching and research on the general lines of what I have tried to describe in this lecture are the most important single contributions that we hygienists can bring to the improvement of conditions of industrial life. I think we can greatly help both employers and employed, but only on the condition that we recognize and proclaim our own ignorance. At present, and for some time, perhaps many years, we are and shall be investigators and students. We are not, to adapt a criticism of a character in one of Mr. H. G. Wells's earlier novels, persons in possession of valuable patent rights who require to be treated with. The importance of "nerves" has been disastrously ignored, mistaken, and derided; let us look to it that we do not fall into the opposite error, by exaggerating the value of what we know and encouraging ourselves or others to fancy that one set of witch doctors can be replaced by another set."

On Friday, May 15th, and Monday, May 18th, lectures will be given, at 8 p.m., by Professor E. L. Collis, on "The coal miner—his health and occupational diseases." Particulars of Chadwick Public Lectures may be obtained from Mrs. Aubrey Richardson, at the offices of the Chadwick Trust, 204, Abbey House, Westminster.

Birmingham General Hospital

In the 151st annual report of the General Hospital, Birmingham, which covers the year 1930, it is announced that the opening of the new casualty department, three wards, and other extensions last November has proved highly satisfactory, enabling treatment to be given to patients more expeditiously and under greatly improved conditions. The additional sixty beds so obtained have rendered it possible to deal with nearly all the cases on the general medical and surgical waiting lists. The number of patients who have had to be referred to other institutions for treatment has been reduced, and the waiting list now consists mainly of those who require treatment in the special departments. The new classrooms and the nurses' recreation hall are meeting the steadily increasing demands for rooms for medical, nursing, and massage examinations, as well as for other educational purposes. The financial outlook is, however, very serious, since there is an overdraft of £20,000 in excess of the remaining unsold free investments. The Queen's Hospital is suffering in a similar way, and representatives of the two institutions are consulting with the Birmingham Hospital Council as to the steps to be taken to deal with the emergency. The total number of in-patients and out-patients in 1930 was 66,964, which constitutes a "record," rising even above the peak figure in 1926.

Birth Control Clinics

In a memorandum (153/M.C.W.) addressed to maternity and child welfare authorities, the Minister of Health states that the Government has had under consideration the question of the use of institutions controlled by local authorities for the purpose of giving advice to women on contraceptive methods. So far as maternity and child welfare centres (including ante-natal centres) are concerned, these centres can properly deal only with expectant mothers, nursing mothers, and young children, and it is the view of the Government that it is not the function of the centres to give advice in regard to birth control, and that their use for such a purpose would be likely to damage the proper work of the centres. At the same time the Government considers that where there are medical grounds for giving advice on contraceptive methods to married women in attendance at the centre it may be given, but that such advice should be limited to cases where further pregnancy would be detrimental to health, and should be given at a separate session and under conditions such as will not disturb the normal and primary work of the centre. The Minister will accordingly be unable to sanction any proposal for the use of the centres for giving birth control advice in other cases. The Government is advised that local authorities have no general power to establish birth control clinics as such, but that under the Notification of Births (Extension) Act, 1915, which enables local authorities to exercise the powers of the Public Health Acts for the care of expectant mothers and nursing mothers, it may properly be held that birth control clinics can be provided for these limited classes of women. Having regard to the acute division of public opinion on the subject of birth control, the Government has decided that no departmental sanction which may be necessary to the establishment of such clinics for expectant and nursing mothers shall be given except on condition that contraceptive advice will be given only in cases where further pregnancy would be detrimental to health. Under the Public Health Acts, local authorities have power to provide clinics at which medical advice and treatment would be available for women suffering from gynaecological conditions. But the enactments governing the provision of such clinics limit their availability to

persons, and the Government has decided that any departmental sanction which may be necessary to the establishment of such clinics shall be given only on condition (1) that the clinics will be available only for women in need of medical advice and treatment for gynaecological conditions, and (2) that advice on contraceptive methods will be given only to married women who attend the clinics for such medical advice or treatment, and in whose cases pregnancy would be detrimental to health.

The Health and Cleanliness Council

The annual luncheon of the Health and Cleanliness Council was held at the Holborn Restaurant on March 26th, and was presided over by Dr. G. F. Buchan. It was attended by a large number of medical officers of health and social workers. The principal address was given by Mrs. Leah Manning, M.P., past-president of the National Union of Teachers, who spoke on the teaching of health and cleanliness in the schools. Cleanliness, she said, was, happily, about the hardest habit to break, but under modern conditions of life, so far as large numbers of elementary school children were concerned, unless they were given a taste for cleanliness in schools, the habit was never likely to be acquired. Many of them came from slum tenements, which afforded no opportunity for cleanliness, and often none for decency. She stigmatized the washing arrangements in many schools—the couple of roller towels to serve a hundred or more children, and the mouldy pieces of soap. Dr. Buchan reminded the company that this was the fifth annual meeting in connexion with this movement. Although it had both words in its title, the council believed that health and cleanliness were synonymous terms. Sanitation was a common-sense application of cleanliness. A clean skin tended to disinfect itself. The idea of cleanliness as a social virtue had been kept well forward by the council. Among other means of propaganda, several films had been produced, one of them entitled "Health is happiness." In eighty-four instances in the mining districts of England and Wales pithead baths had now been provided, and the influence of the council had been used, directly and indirectly, towards achieving that result. Cleanliness in food handling was another subject which had received attention. Tests had been devised, which he hoped would have a psychological effect at least, for use in factories where food was prepared. In some other countries those who handled food were not permitted to follow their calling until they had been certified. The work of the council during the year had increased, and it was becoming impossible to meet all the demands now made for propagandist literature. This year it was hoped to concentrate more than in the past on the school child, and the help of teachers was being enlisted to an ever-increasing extent.

Scotland

Congress of Obstetrics and Gynaecology

The eighth British Congress of Obstetrics and Gynaecology will take place in Glasgow on April 22nd, 23rd, and 24th, by invitation of the Glasgow Obstetrical and Gynaecological Society, whose president, Dr. David Shannon, will act as chairman. This congress is organized under the auspices of the following constituent societies: Section of Obstetrics and Gynaecology, Royal Society of Medicine; Edinburgh Obstetrical Society; North of England Obstetrical and Gynaecological Society; Glasgow Obstetrical and Gynaecological Society; Ulster Medical Society; and the Section of Obstetrics and Gynaecology, Royal Academy of Medicine in Ireland. The principal sessions will be held in the Lister Memorial Lecture Hall of the Royal Infirmary. Both sessions on the first day will be devoted to the clinical and pathological features of ovarian tumours (excluding endometriomata). This discussion will be introduced by Professor Blair Bell, followed by Professor Beckwith Whitehouse, from the clinical side, and Mr. T. G. Stevens, from the pathological side. The morning and afternoon sessions of April 23rd will be opened with papers by the two congress guests, Professor S. A. Gammeltoft, on the teaching of obstetrics and gynaecology as practised in the University of Copenhagen, and Professor H. Guggisberg, of the University of Berne, on conditions of life and reproduction. The afternoon session will be held in the Anatomical Institute of the University, where Professor Bryce will afterwards demonstrate the famous Hunterian collection of anatomical and pathological preparations. The last formal session will be held on the morning of April 24th, the afternoon being devoted to visits to the various hospitals within the city and attendance at operations. A special museum is being organized for the congress in the Pathological Institute of the Royal Infirmary, and the social side has been very well provided for. For those who may be able to remain in the North until Saturday, April 25th, an interesting function has been arranged. For some time the obstetrical societies of Edinburgh and Glasgow have considered the renovation of the tomb of Dr. William Smellie at Lanark. The new memorial will be ready for unveiling in the cemetery of St. Kentigern at noon on that day. The secretaries of the congress are Professor James Hendry (7, Clairmont Gardens, Glasgow, C.3) and Dr. John Hewitt (16, Whitehill Street, Glasgow, E.1), from whom further information may be obtained.

Egyptian Clinical Surgery

A lecture on clinical surgery in ancient Egypt was delivered to the Glasgow Egypt Society on March 17th by Dr. John D. Comrie. The principal part of the lecture dealt with a surgical papyrus published last year by Professor J. H. Breasted of the University of Chicago. Dr. Comrie said that the material of this treatise, known as the Edwin Smith Papyrus, was supposed by Professor Breasted to have come down from a very early period, perhaps 2800 B.C., and the present copy was probably made about 1700 B.C. In some 377 lines the ancient Egyptian scribe had given the record of forty-eight clinical cases, dealing systematically with injuries from the head through the neck and chest to the spinal column. The papyrus at this point had broken off suddenly, which was a misfortune to our knowledge of what the ancient Egyptians might have had to say about the surgery of the abdomen and lower limbs. The surgeon had described the examination of the patient, and the information that might be elicited by questioning him or directing him to make certain movements, and importance had been laid upon examination of the pulse for determining the patient's general condition. This had been the first appearance of the pulse in medical history, more than 1,000 years before it appeared in Greek medicine. Among the mechanical appliances used were absorbent lint, tampons of linen, bandages, surgical stitching—which here had appeared for the first time in surgery—splints, a brace of wood padded with linen for holding the mouth open in a case of tetanus, and a drill for cauterization. The surgeon's favourite remedy for an injury had been "fresh meat" applied for one day only, and followed by an application of lint saturated with ointment and honey. A decoction of willow, which was essentially salicin, had been used as a disinfectant; an ammoniacal preparation was applied to allay inflammation; and as an astringent a solution containing salts of copper and sodium was used. The treatise repeatedly instructed the practitioner to let nature do the work, and in critical cases to adopt a

waiting attitude. After examination, the surgeon had pronounced his diagnosis, and the verdict had been classed as favourable, uncertain, or unfavourable, the latter being expressed in the words "an ailment not to be treated." There were forty-two examples of treatment out of forty-five injuries discussed. In three of these the treatment had been purely mechanical, while in twenty surgical treatment had been combined with the external use of medicaments, and in nineteen external applications had alone been employed. The methods of this early surgeon sounded rational and modern, although his resources were not very great, and there had been an entire absence of the incantations and charms with which other ancient Egyptian papyri abounded.

Mental Deficiency in Scotland

The annual meeting of the Royal Scottish National Institution for Mentally Defective Children at Larbert was held on March 19th. The Earl of Mar and Kellie presided, and Dr. R. D. Clarkson, medical superintendent, submitted the report for last year. Dr. Clarkson stated that the past year had been the seventieth of the institution's existence, and that during its course 560 mentally deficient children of all grades of defect had been cared for. He combated the view, held by many intelligent people, and even by members of the medical profession, that mental deficiency was a hereditary disease. This view, he contended, was wrong, and did an infinite amount of harm. In the great majority of cases mental deficiency was really due to some injury to the growing brain, sometimes caused before birth, sometimes at birth, and sometimes by interference with the blood supply. Many defects arose from a fall upon the head, and others from inflammation of the brain, but heredity accounted for only a small number of the cases. The speaker hoped that the colony for the after-care of patients would soon be ready for occupancy, and he believed that it was better that mentally defective children should be away from their parents throughout their lives, and be cared for by others. He considered that the after-care of such patients was a social function of the very highest value, for defectives who lived in the institution and were given work that they could perform, enjoyed life better than some people who had all their faculties. The chairman stated that the after-care colony was estimated to cost £100,000, and as a result of appeals subscriptions were now available amounting to nearly £40,000. The work of its construction had unfortunately been delayed, but the directors hoped that, when the scheme was completed, it would be opened free of debt. The financial statement showed that the ordinary income had been well maintained.

Edinburgh Women's Hospitals

The annual meeting of the Edinburgh Royal Hospital and Dispensary for Women and Children, and of the Elsie Inglis Maternity Hospital, was held on March 17th, under the presidency of Mrs. J. C. Johnston. According to the report 762 patients were treated in the wards of the Bruntsfield Hospital during the year, while the number of in-patients at the Elsie Inglis Hospital was 1,004, increases of 66 and 34 respectively compared with the previous year. The financial statement showed a slight decrease in income, from £12,814 to £12,387, and a rise in expenditure from £14,328 to £15,836. In referring to radium treatment and research the chairman said that without making any public appeal the committee had been enabled by the generosity of friends to obtain radium to make a beginning with this work. A small ward had been equipped and opened at the end of the past year for radium treatment of cancer cases. She also referred to an investigation in regard to maternal morbidity which had been made at the Elsie Inglis Hospital. In 1928, 667 mothers had been treated in the hospital, with 13 per cent. of morbidity. In 1929, after a certain amount of isolation had been established, the percentage of morbidity had been 9.7, while during the past year, following upon still further precautions, the percentage had fallen to 5.2.

Ireland

Milk and Tuberculosis

At the annual meeting of the Royal National Hospital for Consumption in Ireland, held in Dublin, Dr. T. G. Moorhead, President of the Royal College of Physicians of Ireland, said he was convinced that the slow decline in non-pulmonary tuberculosis was due to the fact that the disease in most cases was caused by drinking the milk of tuberculous cows. Tuberculosis had diminished in Ireland, but the mortality figures were still much higher than those of Great Britain. The decline was due to the diminution of the disease in the pulmonary form. Referring to the Clean Milk Bill, which he believed had been on the stocks for the past two years, he said that when the Government was approached on the subject, the reply always was that there was no time for the Bill. If the public only knew the type of milk that was being sold in many quarters it would force the Government to take action. In regard to the Peamount Colony he hoped that the splendid work being done would soon be made available for suitable patients from all over the country. Dr. Leonard Abrahamson also referred to the holding up of the Clean Milk Bill. Delay in passing this measure into law, he said, retarded the checking of preventable infirmities and of a high mortality. The cause of tuberculosis in children was easily traced to impure milk. In adding his protest to Dr. Moorhead's, and to that of Dr. Wheeler in a letter published in the *Irish Times*, he expressed the hope that every medical man would continue to take similar action until the Bill became law.

The Sanitation of Enniskillen

In a report to the Public Health Committee of the Enniskillen Urban Council the sanitary officer states that none of the slaughterhouses used in connexion with the butchers' shops in the town were found to be suitable for the slaughtering of animals, all being situated too close to inhabited dwelling houses. With one exception, the slaughterhouses, or buildings associated with them, were employed for the storing of hides, bones, cattle offal, and as byres for cattle and sheep. Three were in an insanitary condition, due to the presence or proximity of manure and other objectionable matter. Some of the shops selling milk in the town were also inspected and found unsuitable for this purpose, since proper and separate arrangements had not been made for the keeping of milk in a clean condition. The committee recommended that the council should frame by-laws for the construction, regulation, and control of slaughterhouses in the urban district. In the meantime it suggests that necessary repairs should be carried out, and that the sanitary sub-officer should visit the existing slaughterhouses twice each week and report immediately any case of uncleanliness or insanitation. Where necessary, butchers are advised to provide temporary premises suitable for the slaughter of cattle or sheep. In all cases hides, bones, offal, manure, and other objectionable material must be removed without delay. The committee further recommended that the Dairies and

Cowsheds Order should be enforced, and that dairies or other places found unhygienic should be prohibited from selling milk in the urban district. Dr. Deane of the Ministry of Home Affairs has directed that samples of milk sold in the town should be taken at intervals and submitted to Professor Wilson, Queen's University, Belfast, for bacterial examination. In addition, he has instructed that the results of these tests should be referred to the Public Health Committee, and that persons selling milk found unfit for human consumption should be prosecuted under the provisions of the Public Health (Ireland) Act. Samples of filtered and unfiltered water from the town supply are also to be taken twice each year, and the result of the analyses submitted to the committee and recorded in its minutes.

Londonderry Infirmary

The annual report of the Londonderry City and County Infirmary states that the hospital is now entering upon the 142nd year of its existence. During 1930 the number of patients admitted to the wards was 1,153—8 more than the previous highest figure. Over 900 operations were performed altogether. Although the ordinary expenditure of £7,346 represented an increase of £293, the ordinary income showed an almost corresponding rise, the total amount being £7,320, compared with £7,051 in 1929. Workers' collections amounted to £256, an increase of £60. The report pointed out that although these contributions had increased, the support received was very far short of that accorded to the Belfast hospitals, which derived about £23,000 from this source alone. There was a further increase in the income from the private wards, the total being £1,426, compared with £1,194 in the previous year. Accommodation in the private wards was stated to have been taxed to its utmost for the greater part of the year, and occasional difficulty was experienced in providing beds for all the patients seeking admission.

Correspondence

THE CANFIELD OPERATION FOR PARANASAL SUPPURATION

Sir,—My friend Dr. Perry Goldsmith, in his paper on paranasal suppuration following operation (*British Medical Journal*, March 21st, p. 484), has condensed in small space a huge mass of information and suggestion. His common sense and long experience render this article acceptable both to the learner and to the expert—the former finding answers to many of his existing difficulties and the latter probably finding confirmation of the conclusions arrived at after a more or less successful solution of these difficulties.

I would ask for greater insistence on the value of "operations, such as advocated by Canfield, in which the antrum is entered at the anterior nasal angle," which, as Dr. Goldsmith says, "give a better approach and permit a direct though small view." Instrumentation, he says, may then be carried out, but not in as thorough a manner as he believes should be done.

The point which has struck me most in my experience of the "Canfield operation" has been the unexpected rapidity with which the suppuration has come to an end when compared with my experience of other forms of operation on the antrum. The explanation is, in my opinion, twofold: first, that the opening, whether large or not, lies very far forward in the nasal cavity, and therefore nearer the open air; secondly, that it is situated in a narrow part of the passage, so that the current of air going past it in respiration acts on the antrum like the wind over a chimney or the air in the old perfume spray, drawing the moisture out of the cavity. Whatever the explanation may be, I have no doubt as to the fact, and I feel justified in urging the adoption of the method whenever a decisive result is urgently required or when the suppuration has persisted in spite of the other more usual forms of operation. It is recommended by Halle on the strength of his experience of it in Germany, where it is known as the Sturman-Canfield operation. I described the operation in the *British Medical Journal* of November 10th, 1923, with a series of illustrative cases.

Even if the view obtained is a small one it is sufficient, and the amount of antral instrumentation called for is less than is practised in the other somewhat simpler operations.—I am, etc.,

London, W., March 28th. JAMES DUNDAS-GRANT.

THE THYMUS

Sir,—Your remark that "it seems to be impossible to obtain precise figures for the normal size, shape, or weight of the [thymus] gland at different ages, which can be agreed upon by anatomists, paediatricians, and radiologists," is no doubt a truth, but an unhelpful truth. I should think it would seem to be impossible to obtain a precise translation of a passage in Hippocrates which can be agreed upon by three groups of persons unacquainted with the Greek language. More helpful truths are: (1) complete proof has been given that there is no significant relation between the weight of the thymus and the existence of any "symptom-complex," or any particular manner of dying; (2) complete proof has been given (by Professor J. A. Hammar of Upsala, whose magnificent work it is intellectually discreditable to ignore) that no histological peculiarities of the thymus can be used as diagnostic criteria of status thymicus.

A correspondent of yours has, I think, done a little injustice to the committee set up by the Medical Research Council and the Pathological Society. He seemed to think that the committee wished to prevent expert witnesses and others from talking nonsense about status thymicus. All the committee seems to have suggested is that they should abstain from talking a particular *kind* of nonsense which can be shown to be nonsense. Nobody would even *wish* to prevent experts talking about "hyperthymization, dysthymization, hormonal dysharmony, and an anatomical nervous theory." It comforts the laity, and gives much quiet amusement to physiologists like the late Professor G. N. Stewart, who confessed that "the physiologist can scarcely escape the feeling that here he has broken through into an uncanny fourth dimension of medicine, where the familiar canons and methods of scientific criticism are becoming foolishness, where fact and hypothesis are habitually confounded, and nothing is but what is not."—I am, etc.,

Loughton, March 28th. MAJOR GREENWOOD.

THE PROSTATE IN GENERAL PRACTICE

Sir,—Mr. Kenneth Walker's article in your issue of March 21st, while obviously of immense practical value to those engaged in general practice, opens up questions that concern those engaged with other special territories. With such a contribution touching on various aspects of disease, I apologize for drawing attention to what may appear a trivial point. The subject of chronic prostatitis, we are told, "may appear . . . as a case of 'sciatica,' or of 'chronic rheumatism.' . . . Sometimes . . . disguised as one of recurrent iritis. . . . The prostate is most commonly the primary focus of infection in cases of chronic fibrositis or synovitis."

It would thus appear that a chronic septic infection of the prostate is one of the most frequent causes of its hypertrophy, the analogue of chronic tonsillar sepsis. One may inquire whether the route of infection is infection entering like the gonococcus, from without, or by infection by organisms excreted by the kidneys, or do blood-borne organisms directly involve the prostate?

One would like to learn whether, in a series of cases of chronic prostatic hypertrophy, there is a large percentage with a *previous* history of septic infections of the throat, nose, or teeth, of appendicitis, cholangitis, and so forth. It may be that the prostatic infection is not seldom secondary to another primary source of infection, and that, like the chronic fibrositis, synovitis, iritis, and so forth, the prostate suffers in common as a *secondary* infection.

Quite recently a colleague came under my care on account of a left-sided ocular affection of long standing, associated with post-nasal catarrh. Exploral suction showed infection of a left posterior ethmoid cell, with *Staphylococcus aureus* and streptococcus. But he had noticed exudation of muco-pus from the urethra on defaecation when his post-nasal catarrh and eye symptoms had become active, so I had a smear culture made from this urethral discharge, and it revealed *Staphylococcus aureus* and streptococcus, and *M. crassus*. Further, I have met with a chronic sinusitis which apparently caused an acute epididymitis in a patient with symptoms of a moderate prostatic enlargement.

Such slender grounds do not warrant a theory, but perhaps are sufficient to stimulate inquiry as to the influence of chronic systemic infections as a possible cause of prostatic hypertrophy.—I am, etc.,

PATRICK WATSON-WILLIAMS.

Clifton, Bristol, March 23rd.

THE GENETIC AND RACIAL ASPECTS OF HORMONIC DEFICIENCY

SIR,—As Dr. Manson rightly says, the question raised in my letter of March 7th is of fundamental importance from the racial point of view. It is not limited to cretinism and hypo- or hyper-thyroidism only. Take, for instance, diabetes and insulin deficiency. Dr. Kennedy (*Journ. Amer. Med. Assoc.*, 1931, xcvi), Dr. Joslin, and others have given evidence to show that diabetes has a familial incidence. There must be an increasing number of young diabetics now alive whose symptoms have been relieved, and lives prolonged, by the continued administration of insulin. Some of these patients will have married, and it is very important that we should know to what extent the pancreatic defect is transmitted to offspring. Information is also needed as to the influence of insulin deficiency on reproductive capacity. This point, like that of thyroid defect, might, as Dr. Manson suggests, be cleared up by experimental breeding in animals.

The whole problem is, in fact, a very wide one, and raises the question, What will be the effect on the race of replacing, by artificial means, innate or natural deficiencies which may depend on, or be associated with, genetic factors? Shall we by so doing tend to perpetuate these and other defects in our racial constitution, unless, indeed, other means are employed to counteract this tendency? It is, at any rate, high time that we began to collect the family records and the other data which alone can give us accurate information. Medical men in general practice possess favourable opportunities for doing this, and I would venture to suggest that a collective inquiry by the British Medical Association into the matter would be very useful.—I am, etc.,

Leicester, March 23rd. C. J. BOND.

VACCINE DOSAGE: A PLEA FOR UNIFORMITY

SIR,—Vaccine therapy has now become firmly established in medical practice as a valuable adjunct to therapeutics in cases of chronic infection. And yet it must frankly be confessed that the lack of uniformity among pathologists as to the dosage of autogenous vaccines entirely shakes one's confidence in the scientific accuracy of this form of treatment. A recent experience may give point to this complaint.

It so happens that during the past three months I have had four patients under my care, each suffering from a chronic streptococcal infection of similar character, and for each of whom an autogenous vaccine has been prepared by a separate pathologist of repute and experience. The dosage recommended by these four vaccine experts is as follows:

Pathologist 1:	100,000 streptococci per c.cm.
Pathologist 2:	10,000,000 streptococci per c.cm.
Pathologist 3:	200,000,000 streptococci per c.cm.
Pathologist 4:	400,000,000 streptococci per c.cm.

In no case were the organisms detoxicated.

In other words there is the same difference between the recommendations of the first and fourth pathologists as there would be between one grain of a given drug and half a pound! Is it not high time that some degree of uniformity was arrived at?—I am, etc.,

HAROLD BALME, M.D., F.R.C.S.

Lingfield, March 23rd.

SECURITY OF TENURE IN PUBLIC POSTS

SIR,—Your issue of March 9th, 1929, contained an important leading article on the above subject. In it you traversed some of the more glaring anomalies existing in the conditions of employment under local authorities, and showed that they are not within the ordinary law which regulates the relations between employer and employed. You made several judicious recommendations, among them being:

1. That definite action should be taken to bring these local authorities within the law regulating the relations of employer and employed.

2. That changes in the Superannuation Acts should be effected so that an officer who has completed a certain number of years of service, and is dismissed from his appointment, shall be entitled, in the absence of evidence of misconduct, to a pension in accordance with his years of service.

3. That advertisements for these appointments should indicate that the person appointed will hold office at the pleasure of the employing committee.

Two years have passed since your leading article appeared, and it is perhaps a matter for regret that none of the above recommendations have been given effect. In particular, one cannot help noticing that advertisements, which you then rightly termed "misleading," still continue to appear. For the sake of our younger brethren who may be contemplating entering these services the conditions of employment should be correctly stated.

The aspect of the matter which causes greatest uneasiness is the total lack of security of pensions, though contribution to the superannuation schemes is strictly compulsory. If an officer is dismissed arbitrarily he forfeits all his years of service towards pension. As you say, this is inequitable, and the officer should, at any rate, get a pension in accordance with his years of service. It has generally been assumed, however, that an officer's pension, at least, is safe after he has completed the statutory years of service, and attained the statutory age. A recent ruling has come to my notice which shows that this is not so. The pension of an officer who continues to serve after statutory qualification is just as insecure as that of an officer who has not yet fully qualified. In

both cases alike, termination of the appointment estops any claim to superannuation. Similarly in the case of sick pensions: if an officer continues to serve after he has become entitled to a sick pension on medical grounds, and the authority subsequently sees fit to terminate his appointment, his claim to a sick pension is thereby forfeited.

To many it may seem that such risks as these are infinitesimal; but, in fact, it is not so. Illustrative cases are by no means rare, and they may be expected to go on occurring until adequate legal safeguards are obtained for all employees of local authorities. In the meantime, the moral would seem to be that officers should retire on qualifying for pension.—I am, etc.,

Wedmore, March 22nd. H. C. McMANUS.

CALCIUM METABOLISM

SIR,—The interesting and important Hastings Lecture by Professor Edward Mellanby, which appeared in the *Supplement* of March 21st, induces me to draw attention to the remarks I made on the importance of calcium metabolism in my article on calcium iodide, which appeared in the *British Medical Journal* of July 21st, 1906.

"From foetal life, when we find the early deposition of spicules, to the period of old age, when the bones become . . . brittle, calcium plays an important part. In infancy when the bones are growing, and at puberty when growth ceases, calcium is always exercising a great influence. The proportion between animal and earthy matter in bone is constantly varying from infancy onwards, and disease attacking . . . at an early stage produces quite different effects from those produced at a later period. . . . The chemical products resulting from any disease occurring in a child with rickets where the calcium salts are depleted . . . must be very different from those produced by the same disease in an otherwise healthy child. . . . If [as Dr. Ringer pointed out] ova . . . and red corpuscles . . . are so dependent on . . . calcium salts, it is a logical conclusion that the growth of all cells is dependent on the proper proportion of the same salts. If the normal growth of cells is so dependent, any abnormal growth of cells must depend on some abnormal percentage of calcium."

Since then you have allowed me on many occasions to emphasize the important connexion between the calcium salts and disease, especially rheumatic fever and chorea, a connexion which many investigators, including Professor Mellanby, now appreciate.

An article by me on "The lack of calcium salts in the food of troops on active service," published in *The Hospital*, February 4th, 1911, includes the following statement, which is emphasized with great force by Professor Mellanby.

"The food of the poor is conspicuous by the absence of these most nourishing foods—milk, eggs, and cheese—and as a consequence we find among them a high infantile death rate. . . . That a deficiency of lime salts does predispose to disease is evidenced by the large amount of intestinal troubles that arise in rickety children, and the inflammatory conditions that follow a depletion of calcium salts."

—I am, etc.,

Swansea, March 23rd. G. ARBOUR STEPHENS.

DIET AND HEALTH

SIR,—The *Supplement* to the *British Medical Journal* of March 21st contains a report of Professor Edward Mellanby's lecture on the above subject, and in the same issue of the *Journal* there is a leading article discussing Mrs. Mellanby's experimental work on dental caries. It is a great triumph for these research workers to be able to produce such helpful proved experimental results; and it points the way to prevention of certain diseases in the future. But for the general practitioner, dealing with the problems of disease at the present day, are the various lines of treatment suggested always feasible? My experience is that they are not.

The diet of the people of the Island of Lewis, an isolated community, is quoted as producing strong, healthy, sturdy men, with perfectly formed teeth, and this is put down to the vitamin content of their food, derived from fish liver, etc. But such has been their diet for generations. When we have to deal with those who have lived on the mainland—and especially in towns—we are faced with quite a different problem. Here we have people who have not led the free, open-air life of these islanders (barefoot half the year, and so getting the beneficial effect of the sun), nor practised correct dietetics from generation to generation. The result is an altered biochemical machine to work on, resulting in different constitutional types, with this or that form of allergic manifestation. Every practitioner meets daily with patients who cannot take milk, cream, or eggs, whereas the mere thought of oily things, and particularly cod-liver oil, nauseates many of them. The only result, if one attempts to override this inherent repugnance, is to upset the liver; and acidosis is easily produced with concentrated vitamin D in such subjects. As has been pointed out so often recently in the literature, the giving of glucose and alkalis is a godsend to many of these children. Can we prevent children being born with such a diathesis by supplying the pregnant mothers with suitable diet? In a great many instances the mothers are as difficult as the children.

It would seem, therefore, that we are generations too late with this new-found knowledge, and that we cannot retrace the wrong dietetic path pursued for several generations, just as in the case of the adolescent parenchymatous goitre, which cannot now be remedied because the opportune moment for supplying sufficient available iodine in early years has been lost. "Agrestis," in his letter on "The enigma of the chilblain," on page 516 of the same issue, sums up the case concisely when he says: "If one has a disease one learns a good deal about it."—

I am, etc.,

Darlington, March 25th. R. CHALMERS.

Obituary

JOHN BINFORD BARNETT, F.R.C.S.

RESIDENT SURGEON, ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, COUNTRY BRANCH, STANMORE

We regret to record the death of Mr. John Binford Barnett on March 27th at the early age of 38, at the country branch of the Royal National Orthopaedic Hospital, Stanmore, Middlesex. He was educated at Birmingham University, and proceeded later to the Middlesex and St. Mary's Hospitals. On the outbreak of war Barnett joined the East Lancashire Regiment as a combatant, but after a prolonged illness, from which he never completely recovered, he was invalided out of the Army. He went back to his medical studies and qualified with the M.R.C.S. and L.R.C.P. diplomas in 1918, whereupon he applied for readmission to the Services. He was accepted and given a commission in the medical branch of the Royal Air Force and reached the rank of captain; later he even obtained a pilot's certificate. After the war he held resident surgical appointments at the General Hospital, Birmingham, and the Royal National Orthopaedic Hospital; and clinical assistantships at Great Ormond Street Children's Hospital and Middlesex Hospital.

At the termination of his house-surgeonship at the orthopaedic bospital he was appointed surgical registrar, and in 1923 went to Brockley Hill, Stanmore, as the medical superintendent and resident surgeon of the newly formed country branch. This open-air appointment was much to his liking, in view of the capricious state of his

health. The hospital started off with thirty beds housed in a converted mansion and a large wooden army hut. Soon, however, greater accommodation was required, and Barnett threw himself whole-heartedly into the scheme for providing a model country hospital with permanent buildings, and under his able guidance a fine modern institution of 280 beds gradually grew up. Meanwhile, in 1925, he obtained the F.R.C.S.Eng. He had acquired a large and varied experience of orthopaedic surgery, but perhaps his main bent was in the direction of the surgical treatment of tuberculosis of the bones and joints. He was well abreast of the best work in this branch, and was reaching out along lines of his own. A skilful operator, he had already achieved considerable success in the operative treatment of spinal disease, using a short double bone graft restricted to two or three vertebrae where the disease is limited, and, following Hibbs, he was particularly partial to bone graft arthrodesis in hip disease in selected cases. In addition to administering the hospital, he periodically attended orthopaedic clinics in the Home Counties and on the South Coast in his capacity as visiting surgeon, his opinion being greatly valued by practitioners in these centres. Away from his work he was a keen motorist. In earlier days he rarely missed a meeting at Brooklands, and when his summer vacation came round he regularly took his car across the Channel. Few of his countrymen had a more intimate knowledge of odd corners of France and Spain ; he had been in his car everywhere. He was a good mechanic ; the Brockley bed for the easy nursing and quick transport of patients about hospital grounds is the result of his inventive genius.

Barnett had a high sense of duty, and this, with his tact and sympathetic handling of patients and staff, peculiarly fitted him for the post he occupied, for he was beloved by his patients. Those who knew him best knew how much he periodically suffered from the relics of his old illness, and yet his appearance and manner often belied his symptoms, for he was always engagingly humorous and cheerful. His passing at so early an age is a heavy blow to the Orthopaedic Hospital, and his place will not be easy to fill.

Dr. WILLIAM IRELAND DONALDSON, who died in Dublin on March 15th, aged 68, was the second son of the late Dr. Robert Donaldson of Castleshane, Monaghan. He was educated at Trinity College, Dublin, and graduated M.B.Dub. in 1885, B.Ch. in 1886, and proceeded to the M.D. in 1897. After qualifying, he joined the mental hospital service of the London County Council, and served for some years as senior medical officer to Cane Hill Mental Hospital, and subsequently became medical superintendent of the Manor Mental Hospital, Epsom, where he served for over twenty years. During the war he held a temporary commission as lieutenant-colonel in the R.A.M.C., and served as officer in command of one of the war hospitals in London. On retirement he went to live in Dublin.

We regret to announce the death, at the age of 65, of Mr. ARTHUR HOPEWELL-SMITH, M.R.C.S., L.R.C.P., L.D.S., who was very well known for his work in dental histology and pathology. He was honorary secretary of the Section of Odontology at the Annual Meeting of the British Medical Association in London in 1910. Mr. J. G. Turner, F.R.C.S., sends the following appreciation: Scarcely a year ago Hopewell-Smith relinquished his post as professor of dental histology in the University of Pennsylvania, an appointment he had held since 1914, and returned to London to spend his well-earned leisure amid his old haunts and among his old associates. Before being invited to Pennsylvania he had been lecturer on dental anatomy and demonstrator of dental histology at the Royal Dental Hospital of London, and it was the striking excellence of his practical work in preparing sections of dental tissues and in photomicrography that led to the offer of a post in the United States. His return was hailed with the sincerest pleasure by his old friends, who found the same delightful comrade and enthusiast as of old. They looked forward to a renewal of the days when an outspoken, but always good-humoured, wrangle would be followed by an impromptu pianoforte variety entertainment of which no professional need have been ashamed. Hopewell-Smith leaves behind him an enduring monument in his work in dental histology, but those who knew him best will think of him as a friend whose kindliness and cheerfulness were unfailing.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on March 28th the following medical degrees were conferred:

D.M.—D. G. Leys, R. Lewthwaite.
B.M.—T. M. Davie, E. Harvey, K. N. Irvine.

UNIVERSITY OF LONDON

It has been decided to institute a University Chair of Experimental Pathology, tenable at the Cancer Hospital, Fulham Road.

The University College Committee has re-elected Viscount Chelmsford as chairman and Sir John Rose Bradford as vice-chairman for 1931–32.

VICTORIA UNIVERSITY OF MANCHESTER

Elsie Catlow has been approved at the examination for the Diploma in Public Health, Part II.

UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated:

M.D.—S. J. Hartfall (with distinction), J. C. Lamont, W. A. D. Lawson.

FINAL M.B., CH.B.—*Part I*: H. Agar, Doris B. Brown, H. Featherman, E. Gledhill, J. S. Gourlay, Gwendolen Harrison, H. Hart, F. R. W. Helmsley, Ruth Hooton, E. James, M. Lask, J. Littlewood, I. Macpherson, J. Q. Mountain, I. Rosenberg, M. Rosenthal, L. W. Russell, M. Shankhla, S. Strasburg, S. Suvi, J. Taylor. *Part II (New Regulations)*: J. E. Abell, P. R. Allison, E. L. Brittain, J. M. P. Clark, J. L. Coleman, F. B. T. T. Drake, J. Fielding, L. Glick, R. A. Hall, G. P. Holderness, J. M. Holmes, G. Hyman, G. Marquis, H. Mattison, M. R. Potter, L. J. Richmond, S. Rosenbloom, N. Ross, J. Scholefield, B. Schroeder, P. Science, J. Shapiro, F. R. Staub. *Part III (New Regulations)*: P. R. Allison (first class honours), J. E. Abell, E. L. Brittain, J. M. P. Clark, J. L. Coleman, F. B. T. T. Drake, J. Fielding, R. A. Hall, G. P. Holderness, G. Marquis, M. R. Potter, L. J. Richmond, S. Rosenbloom, N. Ross, J. Scholefield, P. Science, J. Shapiro, F. R. Staub. *Part III (Old Regulations)*: J. Kak.

B.Sc. (with honours).—*Bacteriology, Class I*: K. I. Johnstone.

D.P.H.—H. S. Carter, R. C. Holderness.

The following scholarship and prizes have been awarded:

Infirmary Scholarship: R. L. Lamming. Littlewood Prize: R. L. Lamming. Scattergood Prize: J. Scholefield. Edward Ward Memorial Prize, P. R. Allison. Hardwick Prize, P. R. Allison. McGill Prize: P. R. Allison, J. Scholefield.

The Services

ROYAL NAVY MEDICAL CLUB

The annual dinner will take place this year at the Trocadero Restaurant, Piccadilly Circus, on Thursday, April 16th, at 7.30 for 8 p.m. Members who wish to be present are asked to inform the honorary secretary, Royal Navy Medical Club, Queen Anne's Chambers, Tothill Street, S.W.1, not later than seven clear days before that date.

AUXILIARY R.A.M.C. FUNDS

The annual meeting of the members of the Auxiliary R.A.M.C. Funds will be held at 11, Chandos Street, W.1, on Friday, April 17th, at 5 p.m., when the annual report and financial statement for the year ended December 31st, 1930, will be presented and the officers and committee for the current year elected.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The second reading of the Consumers' Council Bill, the money resolution for the Yarmouth Naval Hospital Bill, the later stages of the Army and Air Force Annual Bill, and other business were set down to be taken in the House of Commons this week before the House adjourned on April 2nd until April 14th. The House of Lords had already adjourned for Easter.

Poisons and Pharmacy Bill

COMMITTEE STAGE IN THE LORDS

On March 26th the House of Lords went into committee on the Pharmacy and Poisons Bill, Lord Ponsonby being in charge of the measure for the Government. On the motion of Lord PONSONBY there was added after Clause 1 a new clause dealing with the issue of certificates of registration and penalties for abuse of certificates.

Lord ASKWITH moved to insert after Clause 3 a new clause to prevent anyone who was not an authorized person under the Act from keeping an open shop for the dispensing of medicines and medical prescriptions. This new clause further required an authorized person who kept an open shop to see that the dispensing should be done by or under the supervision of a pharmacist. He said the amendment would not interfere with the compounding of simple domestic medicines nor with the doctors.

Lord PONSONBY said this proposal had been discussed on March 20th with representatives of the Royal College of Physicians, the General Medical Council, the British Medical Association, and the Society of Apothecaries. Difficulties and objections were raised, and representatives of the medical profession were disinclined to allow the amendment until after much fuller investigation. In these circumstances it was impossible for him to accept it. It would involve hardships in many parts of the country where no registered pharmacist was within reach, and where the proposed clause would prevent the population from getting on a doctor's prescription quite simple remedies involving no compounding, such as cod-liver oil or gargles, and many proprietary medicines. Further, it would apply to the supply of animal medicines on the prescription of a veterinary surgeon. If this amendment were adopted no dispensers holding the certificate from the Society of Apothecaries, and none of the ex-service class of Army dispensers, could carry on the business for which they were well qualified. Lord HEREFORD said that the proposal of Lord Askwith was based on the provisions of the National Health Insurance Act, 1924. The principle had also been recognized in Section 30 of the Pharmacy (Ireland) Act, 1875. Its object was to secure for the remainder of the population the safeguards provided for insured persons by the Insurance Act. Lord PONSONBY said there was no analogy between the two cases. Under the Insurance Act pharmacists could not charge what they liked; their drug tariff was fixed by the Ministry of Health. Under the proposed amendments they would be given a monopoly of dispensing, but there would be no restriction on the prices they might charge. Lord PHILLIMORE recalled that Lord Dawson had said, on second reading, that no medicine should be dispensed except by registered pharmacist or under the supervision of a doctor. Lord PONSONBY replied that Lord Dawson had been unable to come to the conference on the 20th. Other eminent representatives of the medical profession had attended, and expressed the opinion that the amendment suggested by Lord Askwith would not be advisable. Lord ASKWITH then withdrew his amendment.

On the motion of Lord PONSONBY, the House then inserted a new clause to provide that every authorized seller of poisons should send the registrar an annual list of all the sets of premises where he carried on the retail sale of drugs, and also the name of the registered pharmacist by whom each such business was conducted. Amendments were also made to prevent unlawful use of the title "Member of the Pharmaceutical Society," and to make clear that persons who were not registered pharmacists must not describe their premises as a pharmacy.

On Clause 6 (Constitution of Statutory Committee) new subsections were inserted providing that members of the Statutory Committee should hold office for five years. Amendments were made in Clause 10 (conditions to be fulfilled by body corporate in order to become authorized seller of poisons), and on the motion of Lord PONSONBY a new draft was substituted for the original draft of Clause 11 (continuation of business of deceased pharmacist by his representative).

The Poisons Board and the Poisons List

On Clause 15 (preparation of list of poisons for purposes of Act), Lord BERTIE moved to leave out the provision that the Poisons List to be prepared by the Poisons Board must receive the approval of the Home Secretary. He quoted the opinion of Lord Dawson, that the Bill as introduced gave too much power to permanent officials at the Home Office, on whose advice the Home Secretary could overrule the experts on the Poisons Board. Lord PONSONBY retorted that Lord Dawson's opinion had not been reflected by the representatives of the medical profession who came to a consultation regarding the Bill at the Home Office on March 20th. The Government could not agree that the Poisons Board should be sheltered from public control and be sole arbiter on questions of vital importance. Lord HALSBURY, supporting the opinion which had been expressed by Lord Dawson, said there ought to be no authority in Whitehall to override the expert opinion of people who knew best in matters of safety and in health. Lord COZENS-HARDY also supported the amendment. Lord ONSLOW thought the control of Parliament through the Home Secretary should be maintained. The House went to a division in which the original form of words was reaffirmed by 32 to 14, and Lord BERTIE'S amendment was rejected.

Lord PHILLIMORE then discussed an amendment which proposed that the Poisons Board should not be precluded from placing substances on the list by reason of the fact that these were not poisons in the accepted meaning of that term. He said the medical profession would not dispute that substances which were not technically poisons could have an equally deleterious effect on the patient. If persons could be induced to take an overdose of thyroid extract, or an overdose of many other things, they could be killed just as effectively as by putting arsenic in their tea. Lord PONSONBY said that under the amendment it would be possible to schedule alcohol as a poison. He believed that thyroid extract was very popular just now as a means of "slimming," but the conference with the medical profession on March 20th had agreed that if such substances could be shown to be dangerous to life when taken without due care they could be placed on the Poisons List. Lord Ponsonby recalled that, during the second reading, Lord Askwith had suggested that such substances as toxins and thyroid extract might become poisonous when they grew stale. Lord Ponsonby now pointed out that the Therapeutic Substances Act, 1925, gave power to prohibit the sale of such substances after the expiration of a prescribed period from the date of manufacture. If Lord Phillimore desired to have it made quite clear that substances dangerous to life could be scheduled by the Poisons Board, Lord Ponsonby would see that suitable words were put in at a later stage. Lord PHILLIMORE then withdrew his amendment, and also an amendment to divide the Poisons List, Part I, into two classes, sales in the second of which need not be recorded provided requirements as to labelling and containers were observed. Lord PONSONBY said it was better that this question should be left to the discretion of the Poisons Board. An amendment to Clause 16 had been placed on the paper in his name to make clear the discretion of the Poisons Board in discriminating between undoubted poisons and those that were less noxious.

Lord COZENS-HARDY moved an amendment to secure that, unless the Home Secretary could convince Parliament that the advice of the Poisons Board was wrong, he must follow it and make an Order accordingly. This amendment was defeated by 28 to 16.

On Clause 16 an amendment was made, on the motion of Lord HEREFORD and without a division, to ensure that when poisons classified under Part II of the Poisons List were sold in chemists' shops the sale should be by or under the supervision of a registered pharmacist. Other drafting amendments were made on the motion of Lord PONSONBY. Lord COZENS-HARDY was of the opinion that the clause as it stood would compel a doctor who was prescribing for an uninsured person to make certain records and to keep a book, which a doctor

prescribing for insured persons would not have to do. He moved an amendment dealing with this matter. Lord Ponsonby said that the effect of the amendment moved by Lord Cozens-Hardy would be to restrict the conditions about records and books to sales made by pharmacies, and to exempt doctors from their application altogether. That would be going back on existing law. The Pharmacy Act, 1869, required medicines which were needed by a doctor for a patient to be distinctly labelled with the name and address of the doctor, and the ingredients entered, with the name of the person to whom they were supplied, in a book kept by the doctor for the purpose. With regard to insured persons, the National Health Insurance scheme had its own system of records. This particular point had been discussed at the Home Office with representatives of the medical profession, who on the whole preferred not to have any alteration in the present law. The amendment was negatived.

Lord Ponsonby then moved amendments to make clear that a certain subparagraph in Clause 16 did not apply to medical practitioners, and, in the second place, to relax the conditions about recording the details in a book where the medicine supplied was a repeat. Lord Bertie asked whether these amendments would make it unnecessary for a doctor who dispensed his own medicine to put his name and address on the label. Lord Ponsonby said he was not certain on that point; he would see if he could clear the matter up on report. The House then agreed to Lord Ponsonby's amendments.

On Clause 17, which exempts from certain provisions of the Act the sale of poisons wholesale or for export, Lord Ponsonby moved to extend this exemption "to the sale of an article to a duly certified medical practitioner, registered dentist, or registered veterinary surgeon for the purpose of his profession." He said the council of the Pharmaceutical Society was anxious for this amendment. He also had another amendment, to exempt sales of poisons for use in industrial processes—for dyes and matters of that sort. He said such sales had been treated in the past as wholesale transactions. That was not in fact legal, but it was reasonable, and it was desirable to regularize it and make it subject to regulation. Rules would be made with relation to the sale of poisons in trade or business so as to satisfy legitimate industrial requirements. In reply to Lord Henley, Lord Ponsonby gave an assurance that the supply of poisons to duly authorized examining bodies, such as the Institute of Chemistry, for use in conducting examinations would be covered by the Bill as it stood, even though such bodies were not actually teaching institutions. Discussion followed on the clauses dealing with the licensing of persons for the sale of poison substances used for agricultural, horticultural, industrial, and sanitary purposes, and upon the rules to be made by the Home Secretary with regard to such persons and sales. Minor amendments were made in the clauses. Amendments of a drafting character were also made in the clauses concerning penalties, inspection, and the enforcement of the Act. Part of one amendment made on the motion of Lord Ponsonby ran, "nothing in this section shall authorize any inspector appointed thereunder to enter or inspect the premises, not being a shop, of a duly qualified medical practitioner, a registered dentist, or a registered veterinary surgeon."

Constitution of Poisons Board

Debate followed on the constitution of the Poisons Board. Lord Halsbury asked why there should not be a board controlled by experts who really knew. It was an established fact that a particular firm of research chemists in Constantinople had a staff of research chemists doing nothing except to search for new substances in the veronal-medinal group, which was a very dangerous one. These chemists were searching for something which had the same effect as veronal, and for lack of expert advice on the Poisons Board there might be a long delay before the Board dealt with whatever was found by these chemists. There ought to be on the Board representatives of the Pharmaceutical Society, the medical profession, and also the Chemical Society, in order to ensure that such evil substances were at once put on the poisons schedule. Lord Ponsonby, in reply, said that the Home Secretary had agreed that the best possible experts should be appointed to the Board. Official members were already in a majority on the Board as the Bill stood, and the recent conference at the Home Office had agreed that the Board should include an additional representative of the medical profession. The British Medical Association would receive the right to nominate one member. In accordance with this agreement, and on the motion of Lord Ponsonby, amendments were made in the first schedule increasing the Poisons Board from fourteen members to fifteen, and decreasing the number of persons to be appointed by the Home Secretary as additional members from four to three. Lord Henley moved that there be added one person appointed by the Institute of Chemistry. He said the Institute included chemists directly engaged in controlling the manufacture of pharmaceutical preparations containing poisons, and also nearly all public analysts under the Sale of Food and Drugs Acts. Lord Ponsonby said the Government Chemist would be on the Board, but the House agreed to Lord Henley's amendment. On the motion of Lord Ponsonby, a second schedule was added to the Bill regulating the proceedings of the Statutory Committee under the Bill, and prescribing that Regulations should be laid on the table of each House for thirty days before taking effect.

The Bill then passed through committee, and Lord Ponsonby announced that the report stage would not be taken until towards the end of April. Subsequently this stage was put down for April 21st.

Medical Officers in the Air Force.

On March 24th the House of Commons considered the Estimates for the Royal Air Force on report. Dr. Fremantle emphasized the serious deficiency in the supply of medical officers. Mr. Montague, in reply, said there was a deficiency in the number of regular medical officers available. That deficiency was in large part made up by the employment of short-service officers on a commissioned or a civilian basis. The shortage of medical officers in the Services had been referred to a Departmental Committee, which would examine the question as quickly as possible. Recruitment of young medical officers from the Dominions and Colonies was under consideration. Those officers who left the Service after their short commission received a substantial gratuity, and those who remained became permanent medical officers with a good career. Vacancies in the permanent commissioned ranks were filled by selection from those who had been recruited as short-service officers.

Health on Shipboard.—Mr. Graham states that the committee on the health of the mercantile marine has, since February 10th, dealt with proposals for a new scale of medical equipment for passenger ships, recommendations on the medical equipment of coastal vessels, and the revision of the pamphlet dealing with the prevention and treatment of malaria on board ship.

Medical Inspection of School Children.—Mr. Lees-Smith, replying on March 26th to Mr. Herriotts, said that, of the school children who were examined in the course of routine medical inspections last year in the administrative county of Durham, 8,618, or 23.2 per cent., were found to require treatment. The corresponding percentage for England and Wales was 20.8. No information was available as to the total number of children in the county requiring dental treatment, but out of 20,462 children inspected by the school dentists in 1930, 14,218, or 69.5 per cent., were found to require treatment, the percentage for England and Wales being 68.8.

Maternal Mortality in India.—Replying to Miss Rathbone, on March 25th, Mr. Benn said that figures of maternal mortality were not available for the whole of British India, but the ratio of maternal deaths per 1,000 live births in 1927 was 12 for Madras Town, 5.3 for Madras Presidency, 5 for Bombay City and 5.4 for the Presidency. Asked whether these figures were accurate, in view of the statement of the representative of public health in Madras that 20 per 1,000 was a moderate estimate of the number of maternal deaths, Mr. Benn said he had no doubt of their accuracy, but that they did not cover the whole of India.

Notes in Brief.

The Department of Health for Scotland has asked the Kirkcudbright County Council to reconsider its housing programme in the light of a report from its medical officer.

Mr. Shaw states that practically all large countries which are parties to the Geneva Protocol maintain anti-gas establishments and carry out experimental and research work.

Medical News

At the meeting of the Section of Disease in Children of the Royal Society of Medicine, to be held on Tuesday, June 9th, at 8.30 p.m., Professor A. Calmette of Paris will read a paper on B.C.G. immunization of infants.

The Cavendish Lecture, before the West London Medico-Chirurgical Society, will be delivered by Professor Julian Huxley at the Kensington Town Hall on June 5th. The subject will be "Development in relation to heredity and evolution." The annual dinner of the society will be held at the Trocadero Restaurant on Wednesday, July 1st.

At a meeting of the Royal Sanitary Institute on Friday, April 17th, at 5 p.m. in the Guildhall, Poole, discussions will be held on municipal sanitation and on diphtheria immunization at work.

The tenth annual general meeting of the National Institute of Industrial Psychology will be held in the rooms of the Royal Society, Burlington House, Piccadilly, W., on Friday, April 17th, at 5 p.m. The chair will be taken by Viscount D'Abernon, and Sir Frederick G. Hopkins, President of the Royal Society, will address the meeting.

The second biennial conference on mental health, arranged by the National Council of Mental Welfare, will be held at the Central Hall, Westminster, S.W.1, on May 27th to 29th. The speakers will include Sir Hubert Bond, Mr. C. J. Bond, Dr. H. Crichton-Miller, Dr. J. R. Lord, Sir David Munro, Dr. W. A. Potts, Dr. F. C. Shrubsall, and Professor Zimmern. The subject for discussion is the human factor in (*a*) international problems, (*b*) in crime, (*c*) in industry, (*d*) in social services, and (*e*) in education. Applications for tickets should be addressed to the secretary, the National Council for Mental Hygiene, 78, Chandos House, Palmer Street, S.W.1.

An election of Junior Beit Fellows will take place next July. The value of a Fellowship is £400 per annum, and its usual tenure is three years. Forms of application and all information can be obtained by writing to Professor T. R. Elliott, M.D., F.R.S., honorary secretary, Beit Memorial Fellowships for Medical Research, University College Hospital Medical School, University Street, W.C.1.

The Royal College of Physicians will be closed from Friday, April 3rd, to Tuesday, April 7th, both days inclusive.

The Dental Board has arranged a portable exhibit consisting of a series of models showing the development and eruption of the teeth, their structure, and the diseases to which they are liable, which it is prepared to place, together with the services of a trained demonstrator, at the disposal of any health or education authority or other organization concerned with health work, itself bearing all expenditure other than that which is purely local. The exhibit can be readily set up, taken down, and moved from one centre to another, so that it could be used for giving a series of short talks and demonstrations in succession to the children in several schools or the audiences in different public halls. Authorities or societies who think that this service would be of value should make application to the Board at 44, Hallam Street, W.1, stating the period for which it would be desired, and allowing as much latitude as possible in regard to suggested dates.

A course of lectures for medical practitioners on mental deficiency and other mental conditions closely allied to it, supplemented by a course of clinical instruction, has been arranged by the University Extension and Tutorial Classes Council, in co-operation with the Central Association for Mental Welfare. The whole course may be taken, or the two parts may be taken separately. Part I, dealing with mental deficiency, will begin on May 4th and end on May 9th; Part II, in general psychology, will last from May 11th to 16th. All communications should be addressed to Miss Evelyn Fox, c.o. University Extension Department, University of London, South Kensington, S.W.7.

Special summer courses in the French language are to be held at La Sorbonne, Paris, in two sessions, from July 5th to August 24th, and from August 2nd to August 30th, the second session being a shortened one. The courses are divided into three main portions, the first of which comprises either six or four weeks' preparation work in the university coupled with afternoon visits to places of interest in Paris. The second portion consists of thirty-six more advanced afternoon lectures on prominent present-day questions, involving literature, politics, and economics. The third portion consists of a journey, in small groups, into Western France, occupying eight days. The shorter course, however, does not include the journey. Full particulars may be obtained from M. Henri Goy, Directeur du Bureau des Renseignements Scientifiques, Université de Paris, La Sorbonne, rue des Écoles, Paris, Ve.

An international post-graduate course will be held in Vienna, from June 1st to 13th daily, the subject being benign and malignant new growths, with special reference to the early diagnosis of cancer. The pathological, clinical, and therapeutical sides of the whole question will be dealt with in detail. Further information may be obtained from the secretary of the International Post-graduate Courses, Dr. A. Kronfeld, Porzellangasse 22, Vienna IX.

At a recent meeting of the Gosforth Urban District Council Dr. W. Galbraith was presented with an illuminated address and a cheque for 100 guineas on his retirement from the post of medical officer of health after fifty years' service. In commenting on the changes that had taken place in the district since Dr. Galbraith's appointment in 1881, Sir Thomas Oliver said that the present population of Gosforth (about 19,000) had more than quadrupled in the last half-century. During that period Dr. Galbraith had shown unremitting devotion and conspicuous ability in the execution of his duties, and his exceptional experience of a mining district had been of inestimable benefit in safeguarding public health.

The German Association for Internal Medicine will hold a congress in Wiesbaden from April 13th to 16th, under the presidency of Professor von Bergmann of Berlin. The subjects to be considered include the coronary circulation in relation to angina pectoris, nerve control, and the treatment of cholesterin disorders.

The sixth Medical Congress for Psychotherapy will be held at Dresden from May 14th to 17th, under the presidency of Professor E. Kretschmer of Hamburg.

The issue of *Wiener medizinische Wochenschrift* for March 14th is dedicated to the memory of Professor von Basch, the father of clinical sphygmomanometry, who died in 1905.

The London Teachers Association has issued its annual *Register of Recommended Hotels, Boarding Houses, and Apartments* for 1931, which has been revised and brought up to date. The addresses in it have all been recommended by members of that association; and the third-class fares to each of the resorts mentioned are also given, together with a brief note about the local climate and the various facilities. The booklet can be obtained from the offices of the London Teachers Association, 11, Pilgrim Street, E.C.4 (1s. 1½d. post free).

In the course of a health survey conducted in New York City last September by nurses of the Department of Health for the purpose of supplying information desired by the White House Conference on Child Health, an inquiry was made as to the amount of milk used in the different families visited. The survey embraced approximately 14,000 families in various parts of the city, and was so arranged that approximately equal numbers of families of five different socio-economic groups, from the lowest to the highest, were included. The average consumption of milk in the total number of families was found to be 0.98 pint a head per diem. In 1910–14 the consumption was 0.55 pint, and in 1926 it was 0.80 pint.

A museum is to be founded to commemorate Professor Roentgen at his birthplace, Lennep.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Chronic Rhinitis

"G.P." writes: A patient, over 60, who has had chronic nasal catarrh for a lifetime, and a deflected septum, has become depressed and toxic. The discharge is always present, winter and summer. When he has a cold it is intolerable. Vaccines have been tried without success. I should be much obliged for any suggestions how to keep the nose as healthy as possible.

Alcoholism

"A. B. C." writes: Is there any substance which can advisedly be put into alcoholic drinks, such as whisky, in order to engender a distaste in an addict? The case I have in mind is a man over 80, who would not have access to any alcohol except that which is in the house.

Coincident Zoster and Varicella

Dr. S. R. HUNTER (Dunmurry, co. Antrim) writes: An unmarried woman of 74 years for the past fortnight has been confined to bed with a severe attack of herpes zoster; to-day she is covered with a well-developed widespread rash of varicella. Were the shingles the cause of the varicella? There are no other cases of the latter disease in the neighbourhood It must be very unusual to see both diseases at the same time in a patient, and especially one so advanced in years.

Sensitiveness to Sunshine

In reply to the inquiry by "A. S. P." (March 21st, p. 523) for some preparation which would be useful in preventing irritation after exposure to the sun, Messrs. Allen and Hanburys Ltd. suggest the application of an ointment composed of 2 per cent. aesculin in vaseline.

Income Tax

Payment of Interest on Loan

"J. B." has an earned income of £900, out of which he pays £100 interest on loan. Is he entitled to earned income relief on £900 or £800?

*** On £800 only. The other £100 is really income of the lender, and to him is not "earned income" but "investment income," and there are no grounds why *he* should receive earned income relief. It is true that "J. B." has to pay tax on the £100, but that tax he deducts from the interest when he pays it, so that in the long run "J. B." pays tax on £800, having received earned income relief on that amount, and the lender pays tax at the full rate on his £100.

Cost of Books and Subscriptions

[illegible] states that the inspector of taxes has informed [illegible] the purchase of books is not an admissible expense, [illegible] subscriptions unless the membership of the societies [illegible] is an indispensable condition of the employment

*** We presume that the income assessed represents the emoluments of employment rather than the profits of general practice. In that case the inspector's statement is in general true, though in our opinion it would be sufficient compliance with the condition if the appointment was given on the express or *implied* understanding that the applicant would remain a member of the societies in question, and, as regards books possessed, that he would maintain in a reasonably up-to-date condition an appropriate medical reference library. To avoid misleading others, we may perhaps say that the rules with regard to expenses of an ordinary practice are less rigid.

LETTERS, NOTES, ETC.

The Psychiatric Out-Patient Clinic

Mr. C. E. A. BEDWELL (House Governor, King's College Hospital) writes: Dr. Percy Smith, in his statement at the meeting of the Royal Medico-Psychological Association (March 14th, p. 453), seems to have overlooked that King's College Hospital also has an out-patient psychiatric clinic in the same way as the others mentioned in his statement. Surely, too, he was mistaken in saying that there is not a special ward at the Middlesex Hospital for early mental cases.

An Unusual Mental Abnormality

"M. D. E." (London, W.) writes: The sexual abnormality to which Dr. William Brown directed attention in the *Journal* of March 21st is not, I imagine, so very rare. During the last few years two adult men have been under treatment with exactly the same condition described by Dr. Brown. I first came across it years ago, soon after I had qualified, when an elderly man described to me this method of obtaining an orgasm; all his life it had been his sole method of obtaining sexual satisfaction. Minor non-pathological degrees of this sexual variation are common in the form of play among little children and school children. So far as my own investigations go the form described by Dr. Brown becomes established about the age of 5 to 6. Schoolmasters, Dr. Brown suggests, should know how to deal with the "tying-up game." I hope he means that they should understand that it is not a "game" or a "naughtiness" which the schoolmaster should attempt to handle at all; he should be able to recognize that, with the parents' consent, it is a game requiring psychotherapeutic help.

Cornu Cutaneum

Dr. F. A. UNWIN (Fincham, King's Lynn) writes: A man, aged 86, consulted me recently on account of a painless growth on the dorsum of the right hand, which he first noticed twenty years ago, following a knock. On examination the growth was obviously one of cornu cutaneum. The base was discoid and hyperaemic, and measured 2½ by 2 in. The horn was smooth, dark brown, and medullated. The man has spent many years in India. Andrews states that cornu cutaneum is more likely to occur on the scalp and face than in any other location, and sometimes also on the glans penis and scrotum, and that it is usually found in elderly people who have seborrhoea, or who have been subjected to long-continued exposure to sunlight. In most cases cornu cutaneum originates in sebaceous cysts; sometimes in warts, or cutaneous injuries or scars, or in a broken-down molluscous tumour of the eyelids (Jamieson). Whitfield has reported a case in which a horn developed on the site of a cut on the left knee in a patient affected with atrophic lichen planus.

Painless Labour

Dr. JOHN W. S. MCCULLOUGH (Chief Inspector of Health, Toronto) writes: Referring to the letter of Dr. Shortt in the *Journal* of February 14th (p. 294), I recall that some years ago, when in practice, I was called to attend a farmer's wife, a multipara and a most intelligent woman. On inquiry being made as to the character and frequency of her pains, she said "I have no pain," and assured me that she never had any pain in any of her previous (four or five) confinements. The labour progressed with normal uterine contractions to a satisfactory termination, and, much to my surprise, without any sign of pain. In a confinement two years later there was the same absence of pain without any apparent reason.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 52 and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *107*.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

316 The Source of Infection in Tuberculosis

S. LUNDE (*Tidsskrift f. d. Norske Laegefor.*, February 1st, 1931, p. 168) draws attention to the rarity of tuberculosis in cattle in Norway. In the period 1921–27, although 163,349 carcasses were examined in Oslo, Bergen, Trondhjem, and Stavanger, signs of tuberculosis were found only in 258. In 247 of these cases the diseased carcasses were examined in Oslo; in the other three towns there were thus altogether only 11 cases of demonstrable tuberculosis. In the overwhelming majority of these 258 cases the localization and character of the tuberculous lesions showed that they were not likely to be dangerous sources of infection; disease of the udder is rare in Norway. Lunde shows how much more important infection from human sources is by reference to tuberculin tests (Mantoux) with up to 10 mg. of tuberculin. He has examined all the 1,336 children and young persons under the age of 17 in this district, and has obtained a positive reaction in only 130—that is, in 9.73 per cent. In 112 of these cases the source of infection was traced to the positive reactor's home, in 10 to a home in the neighbourhood, and in 2 to a tuberculous school-teacher. In the remaining 6 cases the children had come from another district where the source of infection was unknown. In Lunde's own district, essentially agricultural, there was not a single positive reactor whose infection could be traced to a bovine source. Nearly all the infection was traceable to cases of pulmonary tuberculosis, and Lunde concludes that the most effective means of combating tuberculosis in childhood would be a consistent, deliberate system for the care of human beings suffering from open pulmonary tuberculosis.

317 Prognostic Significance of Precordial Pain

L. LEVIN (*Med. Journ. and Record*, February 4th, 1931, p. 132) has made a survey of a number of patients whose chief complaint was precordial pain. Of 534 private patients who applied for examination and treatment of an actual or fancied heart condition, 68 per cent. were males, as were 75 per cent. of the patients with angina pectoris and coronary occlusion. In this series of cases the incidence of precordial pain was 30.3 per cent. Organic heart pain, particularly that due to coronary occlusion, occurred much earlier and in greater proportions than ordinarily supposed. Dyspnoea was of no value in determining in a given case whether or not the pain had an organic basis. Treatment with xanthine derivatives benefited 63 per cent. of the patients with angina pectoris, 46 per cent. of those with coronary occlusion, and 80 per cent. of those with non-paroxysmal precordial pain of organic origin other than coronary occlusion. At the end of three years' observation 79.3 per cent. of the patients with angina and 38.8 per cent. of those with coronary occlusion were alive. Of these, 60.3 per cent. of the former and 33.3 per cent. of the latter were in good or improved health. Excluding those lost to observation, all of the patients with non-paroxysmal organic pain other than coronary occlusion, and 83.4 per cent. of those with non-organic precordial pain, were in good or improved health.

318 Bulbar Paralysis after Teeth Extraction

W. BAILEY (*Journ. Nerv. and Ment. Dis.*, February, 1931, p. 180) records a case of acute bulbar paralysis, the onset of which directly followed the extraction of teeth. The patient, a woman aged 66, had all her teeth (19) extracted in three sittings. On the day following the last extraction the patient had difficulty in speaking and moving the jaws, and two days later became speechless and developed dysphagia. She complained of severe pain on both sides of the face, especially on the right, and of severe headaches. This appears to be the only case of such a nature to be reported, but facial paralysis following dental extraction has often been noted. Numerous suggestions, here recorded have been made as to the etiology of this facial paralysis. By experiments on dogs Orr and Rows have shown that the lymph stream in nerves is an ascending one, and they believe that toxins could be carried to the cord by this path. Considering the facial pain in the case described here the fifth nerve was apparently irritated on both sides. In view of the large area exposed by the multiple extractions, Bailey suggests that some of the toxins, which were carried along the lymphatics of the fifth and seventh nerves, caused the ensuing bulbar paralysis. In amyotrophic lateral sclerosis and progressive bulbar paralysis the symptoms are predominantly in the motor system, and many investigators think that these diseases may be of microbic origin.

319 Influenzal Polyneuritis

H. OISEAU (*Thèse de Paris*, 1930, No. 483), who records three illustrative cases, states that polyneuritis may develop in convalescence from influenza at periods ranging from 10 days, 3 weeks, 1 month, to 2 months from the onset of the attack. The polyneuritis is principally motor. All four limbs may be affected, and sometimes the disease may assume the course of Landry's paralysis. The muscles of the trunk and neck are very rarely affected. Facial paralysis is fairly frequent, as in 10 cases recorded by Diener 5 showed double Bell's palsy. Several cases of ocular palsy have been recorded, the oculomotor nerve being most commonly affected, while paralysis of accommodation is not frequent. Gradenigo has described a case of post-influenzal auditory neuritis. Palatal and pharyngeal palsies are rare. The characteristic features of influenzal polyneuritis are their predilection for the extremities and especially for the extensor muscles, the frequency of electrical changes, and their irregular course. Sensory, trophic, and vasomotor symptoms are ill-marked. The sphincters are unaffected in most cases. In some cases the cerebro-spinal fluid shows changes similar to those in epidemic encephalitis.

Surgery

320 Fractures at the Upper End of the Radius

J. A. KEY (*Journ. Amer. Med. Assoc.*, January 10th, 1931, p. 101) thinks that, from the standpoint of treatment, fractures of the upper end of the radius fall into three groups—namely, (1) those which should be treated conservatively; (2) those requiring an open operation; and (3) those which should be dealt with on expectant lines, an operation being performed later if necessary. Fractures which should be treated conservatively are fissure fractures of the radial head; chip or chisel fractures of the head in which the detached fragment comprises less than one-third of the circumference of the head, is not displaced, and does not lie against the ulna; and fractures of the neck in which there is very slight displacement of the upper fragment. All that is necessary in these cases is immobilization of the elbow and forearm in a position of moderately acute flexion for two to four weeks. An open operation is required for comminuted fractures of the head of the radius; chip or chisel fractures in which a fragment larger than one-third of the circumference of the head is detached and displaced; and fractures of the neck when the head is displaced downwards, or so tilted as to be unable to rotate on the ulna. In adult patients the head of the radius should be removed, but Key mentions that he has recently replaced it in two cases in children, both of whom have regained normal power and almost complete normal

motility in all directions. Conservative treatment is advised for cases with chip fractures, or fractures of the neck with but slight displacement; chip fractures with considerable displacement of the detached fragment, which may lie loosely in the joint; and fractures of the neck with complete and extensive displacement of the head, which usually lies embedded in the tissues beneath the flexor muscles of the forearm, and can no longer block motion at the elbow. In such cases the final decision regarding the necessity for an operation should be made about six or eight weeks after the injury, and not be put off until traumatic arthritis has ensued.

321 Extravasation from the Ureter

J. F. GEISINGER (*Annals of Surgery*, February, 1931, p. 544) remarks that extravasation from the ureter is an unusual lesion, of grave significance in the absence of trauma; he reports three cases in which the causative factor was apparently necrosis resulting from the impaction of a calculus within the ureter. In such cases the clinical picture will depend upon the amount of extravasation, the virulence of the organisms associated with the lesion, and the tissue reactions of the patient. Although the condition as a rule is imperatively surgical in nature, one of Geisinger's patients recovered without an operation. Catheterization and cystoscopic investigations apparently afforded an outlet for the accumulation on the affected side, thus relieving the patient of sepsis. The author adds that when a patient who is obviously septic presents himself with a history of renal colic, and a physical examination discloses muscular rigidity and marked tenderness in the renal area, posteriorly and anteriorly, or a palpable mass, ureteral extravasation should be borne in mind. Even a radiological investigation may not be conclusive, since the shadow may be wrongly attributed to acute diffuse renal infection, or to ureteral block with acute retention in the pelvis.

322 Pseudomyxoma Peritonei

F. J. IRSIGLER (*Zentralbl. f. Chir.*, February 14th, 1931, p. 408), who records an illustrative case, states that the clinical picture of this condition, which was regarded by Virchow as due to chronic peritonitis with myxomatous degeneration of the peritoneal stroma, was first described by the gynaecologist Werth in 1884. It was initially known only as a sequel of the discharge into the peritoneal cavity of mucus-secreting epithelial cells after rupture of an ovarian cyst, but in 1901 E. Fraenkel described a second form connected with the vermiform appendix, the lumen of which has become obliterated as the result of cicatrization with the formation of a mucocele. Irsigler's patient was a man, aged 20, admitted to hospital with symptoms of acute appendicitis. Laparotomy, which was performed 24 hours after the onset, showed considerable dilatation of the distal end of the appendix and stenosis of the caecal end. Appendicectomy was performed, and recovery was uneventful. F. SCHEWKET (ibid., p. 413) records a similar case in a man, aged 22, admitted to hospital with the diagnosis of chronic appendicitis. On laparotomy the distal end of the appendix showed a bifurcation, one branch of which was empty and presented the usual structure of the appendix, while the other was filled with colloid material. Appendicectomy was performed, and the patient was discharged well in a fortnight.

323 Thyroidectomy immediately before Parturition

R. FONTAINE and R. BAUER (*Bull. et Mém. Soc. Nat. de Chir.*, January 24th, 1931, p. 20) report an unusual case of a large goitre for which a thyroidectomy was performed within a few hours of parturition. The patient, who was the mother of four children, was admitted to hospital with a huge colloid and cystic goitre which was causing severe pressure symptoms. The goitre had been present for several years and had increased in size with each pregnancy, and when seen the patient was suffering from [illegible] dyspnoea, her face and limbs being cyanosed. [illegible] heart sounds could be heard, but it appeared necessary to relieve the asphyxiation of the mother if the child's life was to be saved. The operation was conducted under local anaesthesia, novocain being used with continuous inhalation of oxygen. Thyroidectomy was performed; the goitre, which was found to be multi-nodular and parenchymatous, weighed 600 grams. The respiratory distress was immediately relieved, and six hours after the operation labour pains began. Delivery was expedited by the use of forceps, and two hours later a healthy child was born. Convalescence was normal, except for some irregularity of the heart which necessitated rest. The patient was finally discharged from hospital at the end of six weeks in excellent health.

Therapeutics

324 Treatment of Syphilis

V. G. VECKI (*Med. Journ. and Record*, February 4th, 1931, p. 114) maintains that in the treatment of syphilis there can be no fixed unalterable routine and no stated number of injections; each patient must be studied and treated as an individual case. He regrets that Vernes's test is not more widely employed, because it affords a quantitative as well as a qualitative diagnosis, and enables the degree of infection to be estimated periodically. Using it as a control, patients can be treated until such time as there is some demonstrable certainty that a cure has been obtained. The author uses bismuth in treating all cases of syphilis, and commends the association with it of iodine, given either by the mouth or intravenously. He is satisfied that iodine has a softening influence upon syphilitic foci and a special affinity for diseased tissues which promotes cure. Whenever a case of syphilis is unusually stubborn and resistant to treatment, it is advisable to try a general tonic or an organotherapeutic preparation, since there may be present some active cause apart from the spirochaetal infection. Frequent small doses of antisyphilitic drugs accomplish more than large ones administered at irregular intervals, but before any form of treatment is begun the condition of the patient's kidneys must always be ascertained. Tabetics need special care and precautionary measures, being hypersensitive to physical and chemical irritants, which may provoke angioneurotic attacks. The skin must also be watched, and the occurrence of even slight eruptions be dealt with appropriately. Despite the improvements achieved latterly in antisyphilitic medication, Vecki insists that a syphilitic patient must still be watched and treated from time to time for the greater part of his subsequent life.

325 Treatment of Idiopathic Arterial Hypertension

A. DUMAS (*Presse Méd.*, January 28th, 1931, p. 129) insists that arterial hypertension should be regarded as a disease *sui generis* and not merely as a symptom. The conception of it as a secondary result of renal sclerosis was, he thinks, often due in the past to a misconception of the true sequence of events. Azotaemic nephritis associated with hypertension has now been shown frequently to be the result of hypertension of long standing, and many cases are on record where the arterial tension has fallen to a lower level with the appearance of renal symptoms—one of many evidences of the damage done by the primary disease. There is even some post-mortem evidence, in cases of early hypertension, that the vascular damage can exist without giving rise to clinical signs. Dumas attaches considerable importance to a family history of gout or diabetes in hypertension. In treatment the main aim is to improve the patient's health, and not to reduce the tension; the body has in many cases adapted itself to a certain raised level, and any efforts to bring about a sudden decrease court disaster in the form of vascular thrombosis. It is noteworthy that many patients feel better after rational treatment even when their tension remains unaltered or has increased. The first therapeutic essential is to investigate the past history for gout or glycosuria, and to treat such a diathesis, if present, by appropriate methods of diet. Even if there is evidence

of renal damage, it is not necessary to interdict meat in the diet entirely, nor should the intake of fluids be increased at the expense of solids. When the malady is progressive nervous sedatives and vaso-dilators may be used with advantage, but all methods of producing a rapid fall of tension, especially venesection, must be used with caution. All forms of sepsis should be treated, and the possibility of a preceding syphilitic infection must always be borne in mind; a course of antisyphilitic treatment is often beneficial even in the absence of serological proof of a suspected infection.

326 Salyrgan as a Diuretic

H. B. SPRAGUE and A. GRAYBIEL (*New England Journ. Med.*, January 22nd, 1931, p. 154) record their experience of salyrgan as a diuretic, having tried it in 60 cases over a period of three years. It is a mercurial salt related to novasurol, but apparently less toxic, and is now being used more as a diuretic than as an antisyphilitic drug. It is supplied in 1 c.cm. ampoules of a 10 per cent. aqueous solution containing 37 mg. of mercury, which is 3 mg. more than that contained in an equal quantity of novasurol; 0.5 c.cm. is given intravenously as an initial dose. If by the next day no toxic effects result, such as the occurrence of albumin, casts, or blood in a previously clear urine, or skin or mucous membrane irritation, 1 or 2 c.cm. may be given every three days as long as necessary in the absence of toxic symptoms. In the authors' series 46 of the patients were suffering from congestive heart failure, 8 from hepatic cirrhosis, 4 from cancer, and 1 each from nephrosis and ovarian cyst. Although one-third of these were in the terminal stages of chronic disease the drug produced diuresis in 80 per cent., and in 55 per cent. of the cases this exceeded twice the fluid intake. Its diuretic effect may often be increased by the use of ammonium chloride or nitrate. Very rarely, toxic effects such as mild renal, gastro-intestinal, or skin irritation may occur; careful technique should prevent the occurrence of cellulitis of the arm and thrombosis of the injected vein, which was the only complication in the series.

327 Toxic Symptoms during Cinchophen Administration

L. PARSONS and W. G. HARDING (*Amer. Journ. Med. Sci.*, January, 1931, p. 115) report four cases of cinchophen poisoning in order to call attention to the fact that intensive dosage with this drug, a compound of phenyl quinoline with carboxylic acid, may produce acute hepatic degeneration; long-continued administration of it in moderate doses may result in subacute and chronic hepatic degeneration. They have collected 63 cases in the literature, and classify the toxic symptoms as: (1) cutaneous manifestations, including pruritus, angioneurotic oedema, urticaria, and macular and papular rashes; (2) anaphylactoid reactions indicated by rapid pulse rate and lowered blood pressure; (3) gastro-intestinal disturbances, such as aphthous ulceration of the mouth, pyrosis, nausea, vomiting, and diarrhoea; and (4) hepatic involvement, shown by the appearance of jaundice. In all the fatal cases which have come to necropsy there have been demonstrated striking pathological changes in the liver. In one of the fatal cases reported by the present authors the patient had taken undue doses of the drug supplied in the form of a quack remedy for rheumatism, and they suggest that this danger may be very considerable.

328 Organic Antimony in Kala-azar

E. B. STRUTHERS (*China Med. Journ.*, January, 1931, p. 1) commends neostibosan (a modification of the diethylamine salt of pentavalent amino-phenyl-stibinic acid) in view of its efficacy and comparative freedom from toxicity. The initial dose for an adult was 0.1 gram injected intravenously; it was found better to give injections on alternate days rather than daily. The maximum average dose was 0.3 gram. About 2.6 to 3 grams in all were sufficient for a cure, but sometimes a second course was required after an interval of a month. Owing to the shortage of bed accommodation, treatment was in some cases carried out in clinics, the patients residing temporarily in hostels or inns. The absence of complications was a prominent feature of the treatment.

Disease in Childhood

329 The Pirquet Reaction in Adolescence

A. FOSTRÖM (*Norsk Mag. f. Laegevid.*, February, 1931, p. 148) carried out the Pirquet test in 1,000 training-ship boys, aged from 15 to 19, coming from all parts of Norway, and found that 44.5 per cent. were positive and 55.5 per cent. negative. The frequency of positive reactions was greater in town boys (50 per cent.) than in country lads (37.8 per cent.); labourers' sons gave the highest proportion of positive results (52 per cent.) and peasants' sons the lowest (30 per cent.). Negative reactions were given by 40 boys in whose families one or more cases of tuberculosis and pleurisy had occurred. The reactions between the ages of 15 and 19 years were not so pronounced as in childhood. About 8 per cent. of the negative reactors proved positive when the test was repeated.

330 Acute Haemorrhagic Nephritis in Childhood

A. SUNDAL (*Tidsskrift f. d. Norske Laegefor.*, February 1st, 1931, p. 148) has studied the 51 cases of acute or chronic nephritis treated in the fourteen-year period January 1st, 1916, to January 1st, 1930, in the children's department of the Rikshospital in Oslo. Among these 51 patients there were 41 suffering from acute haemorrhagic nephritis. There were 24 boys to 17 girls, the youngest being 20 months old, and the majority of the patients being between the ages of 3 and 7. The cases were evenly distributed throughout the year, except for an accumulation in September, October, and November. The disease seemed to begin spontaneously in 10 cases, whereas in the remaining 31 it was a sequel to some other complaint—to an angina faucium in 11 cases, to an acute otitis in 7, to abscesses in the skin or glands in 3, to pyrexia of unknown origin in 3, to scarlatina in 3, to enteritis in 2, to parotitis in 1, and to eczema in 1. The part played by scarlet fever was probably underestimated in this material, and in two of the three cases ultimately recognized as being scarlatinal, scarlet fever had not been diagnosed by the doctors sending the patients to hospital. The first sign of the haemorrhagic nephritis was oedema of the face in 16 cases, macroscopic haematuria in 15, and vomiting in 5. Fever, or pain in the epigastrium or albuminuria, was the first sign of the disease in the remaining cases. In about three-quarters of the cases the temperature was normal on admission and remained so; in the remaining quarter the fever was associated with some inflammatory condition, such as otitis, which was doubtless the cause of it. The blood pressure of 24 patients on the day of admission was on the average about 10 per cent. above normal. In May, 1930, 19 of the 41 patients were examined, and perfectly normal conditions were found in 15 cases. In the remaining 4 cases traces of the disease, such as an abnormally high blood pressure or microscopic haematuria, were still demonstrable.

331 Cyclic Vomiting

I. MORGAN (*Med. Journ. of Australia*, October 18th, 1930, p. 527) defines the chief exciting causes of cyclic vomiting in children associated with the excretion of acetone in the urine or in the breath, as fatigue or over-excitement; foods containing a high percentage of animal fat; the onset of an acute infection; teething; constipation; and the arthritic diathesis. Since there is no impairment of the glucose oxidation, and hypoglycaemia is present during an attack, the use of insulin is contraindicated, and the attack can be aborted by giving sugar. Clinical evidence supports the theory that as soon as the glycogen reserve is used up oxidation of fats is incomplete and ketosis occurs. In treating an attack all food should be withheld, and, even though vomiting is frequent, glucose and water be administered continuously in a mixture containing five or six teaspoons of cane sugar in a glass of water with 10 grains of sodium bicarbonate. In severe cases the glucose can be given rectally. In prevention, excess of foods containing animal fats must be avoided, and two or three lumps of sugar may be taken after meals, thus enabling an increased amount of fat to be tolerated. Occasional small doses of sodium bicarbonate may be useful.

Obstetrics and Gynaecology

332 Vaginal Extirpation of Uterus and Adnexa

P. WERNER (*Surg. Gynecol. and Obstet.*, February 1931, p. 233) describes a modification of his method of extirpating the uterus and adnexa on both sides by the vaginal route, by splitting the uterus *in situ* and so extirpating each half with its adnexa separately. Such a procedure is indicated when inflammatory adnexal tumours with perimetrial adhesions are present, and where, owing to the failure of conservative treatment, total extirpation becomes necessary. It is also useful in vaginal hysterectomy for bleeding or for fibroids, and it is especially applicable to cases in which the uterus is fixed. Convalescence is generally rapid, and the danger of peritonitis is absent or very slight. General or spinal anaesthesia is essential, and no special pre-operative treatment is necessary; the experience of many hundred cases shows that any fear of prolapse of the intestine is unfounded. Since it is generally impossible to stop the bleeding completely after freeing inflammatory tumours from their adhesions, the peritoneal cavity must not be closed, but a strip of iodoform gauze is loosely placed therein and led out through the vagina to provide drainage. A portion of this is pulled out and cut off on the fourth day and each day following, so that by the seventh or eighth day the whole of the gauze has been removed. Two days later vaginal douches with potassium permanganate should be given until all discharge disappears. The patient is allowed up on the third or fourth day after operation, and can generally leave the hospital by the eighth or tenth day.

333 Puerperal Infection and Influenza

J. VORON and A. BROCHIER (*Journ. de Méd. de Lyon*, February 5th, 1931, p. 67) define the sources of infection as extragenital, including the skin, mouth, and ears; and genital—for example, vaginitis, Bartholinitis, or other lesions in the genital tract. The fact that these lesions often exist without causing puerperal fever shows that the factor of individual resistance has to be considered, and, moreover, an infection associated with these local lesions is often mild in character. Since puerperal fever is commoner in the winter months when influenza is more prevalent, the authors are inclined to look upon this infection as a potent predisposing cause, which diminishes the local or general resistance. They believe that vaginal examination, with due antiseptic precautions, does not appear to add materially to the risk of puerperal fever, and that there appears to be a definite group of cases which may truly be called autogenous.

334 Early Diagnosis of Extrauterine Pregnancy

S. R. MEAKER (*New England Journ. of Med.*, February 12th, 1931, p. 318), discussing the early diagnosis of extrauterine pregnancy, remarks that the presence of this condition should always be suspected when a woman of child-bearing age exhibits a menstrual disturbance of short duration and pelvic pain of recent origin. If there is no obvious acute inflammation, the existence of any considerable degree of pelvic tenderness, which is aggravated by movements of the uterus, points strongly to the presence of an ectopic gestation. Meaker reports four cases, and discusses the differential diagnosis from such conditions as threatened miscarriage, pelvic inflammation, pregnancy complicated by inflammatory disease, and torsion of the appendages. After discussing the various diagnostic aids, to which he attaches only a limited value, he emphasizes by way of contrast the characteristic nature of the pain; this is irregular in occurrence, severe in degree, and sharp in character, often radiating to the shoulders, the back, or the thighs. It may be superimposed at irregular intervals upon a background of constant, dull [illegible] discomfort. When such a pain is associated with attacks of faintness it may be considered almost pathognomonic.

Pathology

335 The Erythrocyte in Pernicious Anaemia

M. M. WINTROBE (*Amer. Journ. Med. Sci.*, February, 1931, p. 217) discusses the haemoglobin content, volume, and thickness of the red blood corpuscle in pernicious anaemia, and comments on the changes associated with liver therapy. In a series of 100 blood examinations he found that the mean corpuscular volume and the mean corpuscular haemoglobin content were significantly above the normal during relapses. The increase in the mean volume was much greater than the corresponding increase in the average cell diameter, and such volume measurement is therefore commended as being the more useful method of determining the change in the erythrocyte in this disease. The mean corpuscular volume and haemoglobin content were found to be closely correlated with the red cell count, higher values being found progressively as the number of cells diminished. Abnormally high degrees of haemoglobin concentration were not found, and Wintrobe disagrees with the view that in pernicious anaemia there is supersaturation of the red corpuscles. Liver therapy induced decrease in the size and haemoglobin content of the erythrocytes concurrently with the improvement in the total count.

336 Cultivation of Ducrey's Bacillus from Soft Chancres

H. SOSA (*C. R. Soc. de Biologie*, February 13th, 1931, p. 385) noticed that Ducrey's streptobacillus on the surface of blood agar appears in the form of short chains, with the individual members poorly stained or deformed; in the water of condensation, however, it is present in the form of long chains, with the individual members well stained. For this reason he attempted to cultivate the bacillus in a fluid medium. The technique that he found most satisfactory for isolation is as follows. The chancre is thoroughly cleaned with iodine and alcohol on the day previous to examination, and covered with collodion. The pus on the surface is diluted in 0.5 c.cm. of broth, and inoculated into sterile tubes containing 0.2 c.cm. of defibrinated rabbit's blood mixed with 0.8 c.cm. of saline solution. One loopful of the pus suspension is used for inoculation. The tubes are shaken and incubated at 34° C. Films are made after fourteen and twenty-four hours, and stained by Gram's method. Subcultures should be made each day for two or three days, and then inoculated on to blood agar. Usually only one passage in the blood saline medium is necessary to obtain the organisms in pure culture.

337 The Blood Sedimentation Rate in Gynaecological Conditions

A. MATHIEU and others (*Amer. Journ. of Obstet. and Gynecol.*, February, 1931, p. 197), as a result of using the modified Westergren technique of the sedimentation test in over 2,000 estimations, report that the sedimentation rate is increased after the third month of pregnancy and until the fourth week after delivery, and that its observation affords a useful indicator of certain abnormal gynaecological conditions. Thus it is definitely raised when there is haemorrhage, infection, or tissue necrosis, and the degree of increase was found to be definitely proportionate to the severity and extent of the morbid process. The authors demonstrated also that the injection of foreign protein increased the rate. This test is recommended as being of great value in following the clinical course sometimes, especially in cases of salpingitis, and abnormalities which are not satisfactorily explainable should always indicate the need of more exhaustive examination. While there are exceptions to the test being invariably a criterion of disease, it has a very special value in drawing attention to infection or malignancy which might previously have been unobserved otherwise, and the speed with which the test is carried out is an additional merit. The authors remark that repeated determinations on the same individual are essential if the maximum amount of information is to be obtained.

de KUYPER'S
HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopœia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 236 years.

FELAMINE BRAND SANDOZ

SANDOZ

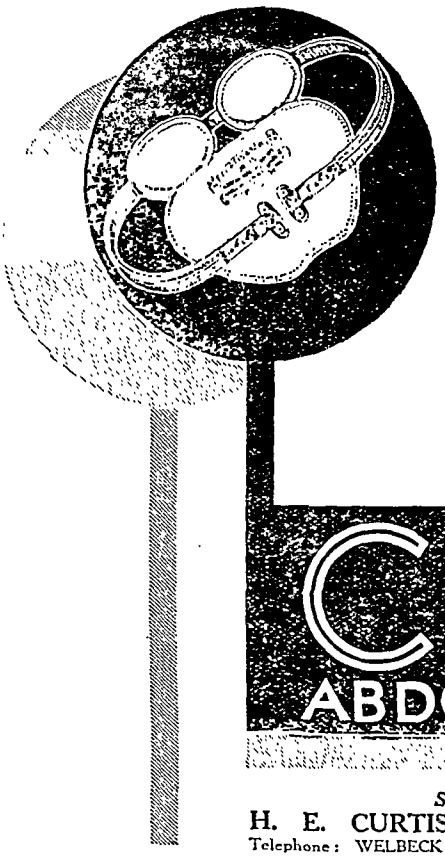
An association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, entirely free from accessory substances.

Indications:

CHOLANGITIS, CHOLECYSTITIS, HEPATIC INSUFFICIENCY, HEPATIC CONGESTION, JAUNDICE, CHRONIC CONSTIPATION.

Felamine is supplied in Bottles of 50 and 250 Tablets.

AGENCY:-
SANDOZ CHEMICAL WORKS PHARMACEUTICAL DEPT.
5, WIGMORE STREET, LONDON, W. 1.



Comfortable, and Correct Support

Assured to all sufferers from abdominal ptosis who wear the Curtis Abdominal Support, Model No. 1. The principle of this support—that of anterior posterior support—has been proved by scientific research to be the most efficient. There is no circumferential pressure, hence the wearer's freedom of movement is in no way restricted. There is no cramping or binding of the hips. It is light in weight, and easy to apply. There are no complicated fastenings.

IN USE IN MOST OF THE LONDON HOSPITALS.

CURTIS

NATURAL APERIENT MINERAL WATER

OF

RUBINAT LLORACH

(Hydragogue, Purgative, and Cholagogue.)

The official analysis shows in each litre about 1601.321 grains of **Anhydrous Salts**, of which are **Sulp. Soda** 1485.368 grains, and **Sulp. Magnesia** 50.301 grains.

Prescribed in cases of Gall-stones, Liver Disease, and threatened Appendicitis, Constipation associated with Gout, Hepatic Dyspepsia, Gastric Fever, and generally in Abdominal Obstruction.

DOSE.

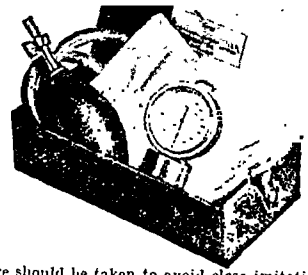
Wineglassful fasting; can be increased according to temperament. Effect is more rapid if followed by a cup of hot tea.

NO GASTRIC IRRITATION. NO ALTERATION IN DIET REQUIRED.

"A moderately powerful stimulant of the liver, and a powerful stimulant of the intestine.

Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.



Care should be taken to avoid close imitations. Look for the trade mark "TYCOS" engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

RE-INFORCING THE ABDOMINAL MUSCLES WITHOUT UNDUE PRESSURE!

For those disorders of the abdomen that call for external support, Domen Abdominal Belts have very definite advantages. They give adequate support to the abdomen without setting up pressure to aggravate the patient's condition. And whether it is pregnancy or umbilical hernia, prolapsus uteri, or simply general support, there is a Domen Belt designed specifically for that condition. Domen Belts fit well, sit comfortably and do not get out of place. They leave the patient free and without embarrassment. Full particulars will be forwarded on receipt of your card or a telephoned request.

BRITISH SPAS
ARE BEST

and membership of the British Spas Federation is a guarantee of efficiency

AT British Spas, treatment is only given (except in a few minor cases) upon medical prescription.

At British Spas the staffs are educated and properly trained and, in some cases, medically trained and medically certificated.

Equipment and administration are thoroughly up to date and scientific. Every new treatment is tested and reported upon before being adopted.

British Spas are also remarkably fortunate as regards situation, scenic beauty and pure air. These factors, combined with the social amenities of a home town, aid the cure considerably.

BATH Hot Springs (120° F.) Radio-active. Royal Baths extensions now open.

BRIDGE OF ALLAN Saline Water. Rich Calcium Bromide and Iodine Content.

BUXTON Radio-active Mineral Water. New Natural Baths. 3 Guineas Course.

CHELTENHAM Five Natural Waters. Modern Baths.

DROITWICH The Brine Baths Spa in charming Worcestershire.

HARROGATE 88 Waters. 100 Treatments. Medically certificated staff.

LEAMINGTON Advanced Spa Treatment. Saline Springs.

LLANDRINDOD WELLS The Modern Welsh Spa.

TREFRIW WELLS Rich Sulphate Chalybeate Waters.

WOODHALL SPA Bromo-Iodine Waters. Pinewoods. Restful Air.

¶ A New Medical Handbook is being published, specially prepared for the use of the medical profession. A copy will gladly be sent you if you will write to the Hon. Secretary, Box 1, British Spas Federation, Pump Room, Leamington Spa, or to the Managers of any of the Spas here mentioned.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

NATIONAL POST-GRADUATE SCHOOL OF RADIOTHERAPY.

The Mount Vernon Hospital and Radium Institute, Riding House Street, London, W.1.
Dean—Sir CUTHBERT WALLACE, K.C.M.G., C.B., F.R.C.S.

An intensive Course in

RADIOTHERAPY

especially in its relation to Malignant Disease

will be held at the above school, commencing Monday, June 1st, 1931. Full particulars will be published later.

The Course will be repeated on subsequent dates.

Applications for copies of the syllabus, etc., may be made at once, and these will be forwarded as soon as available.

The Dean will be glad to see prospective entrants by appointment.

THOS. A. GARNER, Secretary.

County Council of Middlesex.

DISTRICT MEDICAL OFFICER AND PUBLIC VACCINATOR.

The County Council invites applications from duly qualified Medical Practitioners for the undermentioned appointments:

DISTRICT MEDICAL OFFICER, Edgware, Little Stanmore, and Lower Hale (Hendon).

Salary £80 per annum. The officer appointed will be required to carry out his duties in accordance with the Public Assistance Order, 1930, of the Minister of Health, to reside in the district, and to name to the Council some duly qualified Medical Practitioner who will, in the case of his absence or other hindrance to his personal attendance, act in his place.

PUBLIC VACCINATOR, Edgware, Little Stanmore, and Lower Hale (Hendon).

The person appointed will be required to produce to the Council a certificate of proficiency in vaccination, unless such certificate was required as a condition of obtaining any diploma, licence, or degree which he possesses.

He will be required also to enter into a contract with the Council in accordance with the Vaccination Order, 1930, of the Minister of Health. The contract will provide for the payment of the minimum fees laid down in the Order.

Applications, stating (1) name, (2) age, (3) qualifications and experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than April 18th.

No special application forms are provided. Envelopes must be endorsed "District Medical Officer" or "Public Vaccinator" as the case may be.

Canvassing, directly or indirectly, will be a disqualification.

ERNEST S. W. HART, Clerk of the County Council.

Guildhall, Westminster, S.W.1.
March 23rd, 1931.

Scarborough Hospital and DISPENSARY. (70 Beds.)

Wanted May 1st, Two HOUSE SURGEONS (male or female). Duties include home visiting. Salary £175 per annum, with board, residence, etc. Appointment for six months.

Applications, stating age, with copies of testimonials and essential particulars, to be sent to the undersigned by April 15th, from whom further particulars may be obtained.

J. DOUGLAS MUNBY, Hon. Secretary.

The Hospital for Sick Children, NEWCASTLE-UPON-TYNE. (94 Beds.)

Applications are invited for a HOUSE SURGEON (male or female), to commence duties forthwith until September 30th. Salary at the rate of £100 per annum, together with board, residence, and laundry.

Applications, stating age and qualifications, with copies of testimonials, to be sent to the Secretary, Mr. NEIL BROMIE 18, City Road, Newcastle.

UNIVERSITY of CAMBRIDGE.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

The next Course of Study for the Diploma, which is open only to duly qualified Medical Men and Women, begins on October 5th, 1931, and occupies nine months.

During the first three months instruction in Physics is given in the Cavendish Laboratory, and in Elementary Radiology and Electrology in the Department of Radiology at Cambridge. Arrangements are made by the British Institute of Radiology for a similar Course to be given in London at the same time. These Courses are alternative.

The second three months must be spent in London, where lectures are given at the British Institute of Radiology, and are combined with clinical instruction in the large teaching Hospitals.

The third three months may be spent in recognized Hospitals in London or elsewhere, the student acting as clinical assistant or in similar capacity.

The examinations consist of three parts, viz.:
1. Physics, with examinations in January and April.
2. Radiology and Electrology, with examinations in April and July.
3. The presentation of a Thesis which is entirely the candidate's own work, and is intended to show that he has had practical experience of the subjects.

Further information as to the Courses, together with application forms for admission, may be obtained from:

G. STEAD, M.A., Secretary for the Diploma, Cavendish Laboratory, Cambridge, or,
The General Secretary, British Institute of Radiology, 32, Welbeck Street, London, W.1.

Completed forms of application for admission must reach the Secretaries not later than September 10th.

University of Leeds.

POST-GRADUATE COURSES IN OBSTETRICS AND ANTE-NATAL WORK AT THE LEEDS MATERNITY HOSPITAL. (108 Beds.)

Registered Medical Practitioners are admitted to the Hospital Practice, comprising Ante-natal, Labour and Isolation Departments, for periods of 2–4 weeks.

For particulars as to vacancies at the University Obstetrics Students' Hostel, adjoining the Hospital, apply to the DEAN, School of Medicine, Leeds.

June 21st, 1930.

University of Bristol.

The University invites applications for a LECTURESHIP IN PHYSIOLOGY. Salary £300 to £400 per annum, according to qualifications.

Applications should reach the undersigned, from whom further particulars may be obtained, on or before Friday, April 24th.

WINIFRED SHAPLAND, Secretary and Acting Registrar.

Nottinghamshire County Council

EDUCATION COMMITTEE.

ASSISTANT SCHOOL MEDICAL OFFICER (Male).

Applications are invited from duly qualified and registered Medical Practitioners for the post of Assistant School Medical Officer.

Candidates must possess a Diploma in Public Health and have had at least three years' experience since appointed.

The officer appointed will be required to devote his whole time to the duties of the office. He will be a member of the Staff of the County Medical Officer, will work under his control and direction, and will be required to reside in a part of the County to be approved by him and to carry out such duties as may be prescribed.

The salary will be at the rate of £500 per annum, rising by annual increments of £25 to £700, with travelling allowances in accordance with the County Council's Scale.

The engagement will be terminable by three months' notice on either side.

The successful candidate will be required to pass a medical examination.

The appointment is an established post under the Local Government and Other Officers Superannuation Act, 1922.

Applications on the prescribed form (which may be obtained on application to me), accompanied by copies of not more than three recent testimonials, should be forwarded to the County Medical Officer, Shire Hall, Nottingham, not later than April 18th.

K. TWEEDALE MEABY, Clerk of the County Council.

Shire Hall, Nottingham.
March, 1931.

Shanghai Municipal Council

PUBLIC HEALTH DEPARTMENT.

ASSISTANT PATHOLOGIST.

An additional Assistant Pathologist is required in the Public Health Department of the Shanghai Municipal Council.

Candidates, preferably unmarried, should not be more than 30 years of age, and must hold qualifications in Medicine and Surgery of University standard. In addition, they must have working experience of the routine of a Pathological Laboratory, and practical knowledge of the manufacture of bacterial vaccines in bulk is desirable. Experience in Tropical Medicine would be a recommendation.

Salary for three years, Taels 650 per mensem, or Taels 700 per mensem if holding a D.P.H. or its equivalent. Thereafter rising by triennial increments of Taels 100 to Taels 1,250 or Taels 1,300 if with D.P.H., subject to satisfactory service. After six years on the maximum pay, a final long service increase of Taels 100 per mensem is granted. A Tael at the present rate of exchange equals about 1/4d. Exchange is, however, subject to fluctuation.

Service is under Letter of Appointment, which is for three years in the first instance.

Owing to the present adverse exchange rates the Council, under certain limitations, guarantee one-third of pay at the rate of 2/6 to the Tael. Further particulars may be obtained on application.

First-class passage is provided, with half-pay during the voyage, and 7 months' leave is given on full pay, with first-class passage, after every period of 5 years' service in Shanghai.

Free Medical attendance and Hospital accommodation in accordance with the Council's standard rates are provided, and there is participation in the benefits of a Superannuation and Pension Fund.

Full particulars of the vacancy and the Terms of Service in force for Municipal employees may be obtained from the Council's Agents.

Applications, with full information as to qualifications, experience, etc., accompanied by three recent testimonials and endorsed "Assistant Pathologist," should be forwarded to the Council's Agents, Messrs. JOHN POOK & COMPANY, 68, Fenchurch Street, London, E.C.3.

March, 1931.

Borough of Ilford.

APPOINTMENT OF ASSISTANT SCHOOL DENTAL SURGEON.

The Ilford Borough Council invites applications from registered Dental Surgeons of either sex holding a degree or diploma in Dental Surgery for the above appointment.

The inclusive salary of the office will be at the rate of £450 per annum.

The duties of the officer appointed will be mainly connected with the Dental Inspection and Treatment of School Children, but the successful candidate will be required to assist when necessary with the other dental services of the Council.

The person appointed will be required to devote his or her whole time to the duties of the office, to reside within the Borough, to work under the general supervision of the Medical Officer of Health of the Council, and to enter into a contract with the Council for the due performance and fulfilment of the duties and conditions of the appointment.

The appointment will be subject to the Staff Regulations of the Council, and the successful applicant will be required to pass a medical examination.

Candidates must not be more than 45 years of age.

The appointment will also be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, which must be made on forms obtainable (with list of duties) from the undersigned, accompanied by copies of three recent testimonials (which will not be returned), and endorsed "Dental Surgeon," must be received at my office at the Town Hall, Ilford, not later than noon on Monday, April 13th.

Canvassing members of the Council or Education Committee, directly or indirectly, is prohibited and will disqualify.

By Order,
ADAM PARTINGTON,
Town Clerk.

Town Hall, Ilford.
March 26th, 1931.

Clayton Hospital, Wakefield.

Vacancies exist for Two HOUSE SURGEONS (male, British), for which posts applications are invited. The appointments are for six months in the first instance, and the salary for each is at the rate of £200 per annum, together with board, residence, and laundry.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be sent to the undersigned as early as possible.

H. J. LANCASTER, Gen. Supt. and Secretary.

The Gloucestershire Royal Infirmary and Eye Institution, Gloucester.

(155 Beds—4 Residents.)

Applications are invited for the posts of: RESIDENT SURGICAL OFFICER (male). Salary at the rate of £200 per annum. Six months' appointment, with board, residence, and laundry. Good opportunity for Surgery.

First HOUSE SURGEON (male). Salary at the rate of £150 per annum. Six months' appointment, with board, residence, and laundry.

The First House Surgeon will be required to enter upon his duties on April 8th, and the Resident Surgical Officer on April 28th.

Applications, stating age, qualifications, and nationality, with copies of three recent testimonials, to be sent to the undersigned.

The Committee of Management invite applications for the posts of HOUSE PHYSICIAN and HOUSE SURGEON, which will become vacant on April 30th next, and for the post of HOUSE PHYSICIAN which will become vacant on May 31st next.

Applicants (men) must be fully qualified and registered. The appointments are for six months, with board, residence, and washing provided. Salary at the rate of £100 per annum in each case.

Applications, with copies of testimonials, stating age, should be forwarded on or before Friday, April 10th, to the Secretary.

Bury Infirmary, Lancs.

(A General Hospital of 165 Beds.)

Applications are invited for the post of HOUSE SURGEON to Special Departments. The appointment is for six months, at a salary at the rate of £200 per annum, with board, residence, and laundry.

The appointed candidate will be required to commence duty on or about April 26th.

Applications, stating age, qualifications, and nationality, with copies of three recent testimonials, to be sent to the undersigned not later than the first post of Saturday, April 11th, endorsed "House Surgeon."

Particulars of duties may be obtained on application.

ALEX. W. MAITLAND, Hon. Secretary.

Merthyr General Hospital, Merthyr Tydfil.

Applications are invited for the post of RESIDENT HOUSE SURGEON at this Hospital for a period of six months. Salary at the rate of £150 per annum, with board, rooms, and laundry.

Applicants must have had experience in administration of Anæsthetics.

Applications, stating age and qualifications, and enclosing copies (only) of not more than three testimonials, should be addressed Hon. Secretary, Hon. Medical Staff, Merthyr General Hospital.

Victoria Central Hospital, Wallasey.

Applications are invited for the position of JUNIOR HOUSE SURGEON (male). Salary at the rate of £100 per annum, with board, residence, and laundry, with prospects of appointment to Senior House Surgeon in six months' time, at a salary of £150 per annum.

Candidates chosen will be appointed for six months.

Applications, with copies of testimonials, to be sent to the Secretary.

Liverpool Stanley Hospital.

Applications are invited for the post of HONORARY SURGEON.

Applications with qualifications and testimonials, addressed to the President, to be sent to reach him before Saturday, April 18th.

The canvassing of any member of the Election Committee will disqualify, but candidates are at liberty to send to the members copies of their applications and testimonials.

FRANK WHITE, Hon. Secretary.

April 1st, 1931. By Order of the Council. ALFRED COX, Medical Secretary.

Hospital for Consumption and DISEASES OF THE CHEST, Brompton, S.W.3.

The Committee of Management invite applications for the post of HOUSE PHYSICIAN (for which there are three vacancies). The duties include work in the Out-patient Department as well as in the Wards, and one of the selected candidates will also be appointed Assistant to the Tuberculosis Officer for the local Tuberculosis Dispensary at the Hospital. The appointment is for six months, commencing on May 1st, with an honorarium of £50.

Applications are also invited from duly qualified Medical men for the post of JUNIOR HOUSE PHYSICIAN at the Sanatorium at Frimley. The appointment is for six months, commencing on May 1st, with an honorarium of £50. At the expiration of his term of office, or in the event of a vacancy, the Junior House Physician will be expected to apply for and, if appointed, to hold the post of Senior House Physician for a further term of six months.

Applications, with copies of testimonials, must reach the undersigned not later than Saturday, April 11th.

Brompton. March, 1931. FREDERICK WOOD, Secretary.

Oldham Royal Infirmary.

Applications are invited for the undermentioned posts:

HOUSE SURGEON in charge of Women's and Children's Wards.

HOUSE SURGEON in charge of Male Wards.

HOUSE SURGEON in charge of Out-Patients and Special Departments (in this post a knowledge of Refractions is desirable).

Salary £175 in each case, with board, residence, and laundry. Appointments tenable for six months. Successful applicants may re-apply for a further six months' service.

Applications to be submitted forthwith, together with copies of three recent testimonials, to the undersigned.

CHARLES D. DRAKE, General Superintendent.

London Jewish Hospital, Stepney Green, E.1. (General Hospital—108 Beds.)

The Council of Management invite applications for the appointment of HONORARY ASSISTANT PHYSICIAN, who will be required to make two Out-patient visits weekly. Only one session (Wednesday afternoon) is available at present, but the second will be allotted when occasion arises.

Candidates must possess the degree of M.D. or M.B., obtained by examination at a recognised University, and be Fellows or Members of the Royal College of Physicians of London, or Fellows of the Royal College of Physicians of Edinburgh or Ireland, and shall not be engaged in the practice of Pharmacy or Midwifery.

Candidates must send twenty copies of their application, with copies of three recent testimonials, to the Secretary of the Hospital, on or before Friday, April 17th.

South Devon and East Cornwall HOSPITAL, PLYMOUTH. (240 Beds.)

HOUSE SURGEON. *Salary £100 per annum*, with board, residence, and laundry. Appointment is tenable for six months, and is subject to renewal. Duties to commence at once. Candidates must be registered under the Medical Acts.

Applications, stating age and qualifications, together with copies of recent testimonials, to reach the undersigned by April 10th.

ARTHUR R. CASH, Gen. Supt. and Secretary.

March 24th, 1931.

The Royal Aberdeen Hospital FOR SICK CHILDREN.

Wanted, RESIDENT MEDICAL OFFICER, to commence duties on May 1st. Candidates are requested to call on Senior Members of the Hon. Medical Staff. Applications, accompanied by one copy of testimonials, to be lodged on or before Friday, April 17th, with Mr. A. S. R. BRUCE, 12, Dee Street, Aberdeen.

Mansfield and District Hospital.

The Board of Management of the above Hospital (140 beds) invite applications for the post of HOUSE SURGEON and CASUALTY OFFICER (male).

Salary at the rate of £175 per annum, with residence, board, and laundry.

The appointment is for six months and is renewable.

The Resident Staff consists of a Resident Surgical Officer and Two House Surgeons.

Applications, accompanied by not more than three recent testimonials, to be sent to the undersigned.

Dated this 28th day of February, 1931.

ARTHUR H. LIMB, Secretary.

General Hospital, Nottingham.

A HOUSE SURGEON is required at the above Institution. The appointment is for six months, with salary at the rate of £150 a year, with board, residence, and laundry.

Applications, stating age, qualifications, and experience, together with copies of testimonials, to be sent to the undersigned not later than Saturday, April 25th.

The appointment will be made on Wednesday, May 6th.

Duties to commence Saturday, May 16th.

P. M. MACCOLL, House Governor & Secretary.

St. Mark's Hospital for Cancer, FISTULA, AND OTHER DISEASES OF THE RECTUM, City Road, London, E.C.1.

HOUSE SURGEON (male) required. Must be fully qualified. Salary £75 per annum, with board, residence, and laundry. The appointment is for a minimum of six months from May 1st next.

Applications, with copies of testimonials, must reach the Secretary (from whom further particulars may be obtained) not later than 10 a.m. Monday, April 13th.

(Appointments continued on p. 51.)

W. H. GRACE, M.D., M.R.C.P.,
Hon. Superintendent of the Resident Medical Staff.

Borough of Ealing.

MATERNITY AND CHILD WELFARE SERVICES.

WOMAN ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified Medical Practitioners for the position of Woman Assistant Medical Officer.

The duties will mainly consist of work in connection with the Council's Maternity and Child Welfare Scheme, embracing attendance at the Health Centres, supervision of Midwives and Nursing Homes, and medical attendance on patients in the Chiswick and Ealing Maternity Hospital. The person appointed will reside at this Hospital, board and furnished rooms being provided for her.

Applicants must have had previous experience of Maternity and Child Welfare work, and particularly of work in a Maternity Hospital.

The person appointed will be required to devote her whole time to the duties, and will not be allowed to engage in private practice.

The salary will be at the rate of £450 per annum, rising by £25 per annum to a maximum of £550, plus board and residence as indicated above, and valued at £150 per annum. A deduction of 5 per cent. will be made in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to the candidate passing the Council's medical examination in connection therewith. Canvassing will be a disqualification.

Copies of form of application and terms of appointment can be obtained from the undersigned, to whom applications, accompanied by copies of not more than three recent testimonials, must be delivered not later than April 14th

THOMAS ORR,
Town Hall, Ealing, W.5. Medical Officer of Health.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place,

Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

SAVED BABY'S LIFE!

PORTE'S CAESAREAN OPERATION

In 'The Scottish Nurse' for January 1931 appeared an article by a Scottish State Registered Nurse describing an exceedingly severe operation—*Porte's Caesarean Section*—which she underwent in Malta at the hands of a well-known surgeon.

Twenty-four hours after the second stage of labour had begun it was discovered that delivery was impossible. The womb had become septic and the Porte Caesarean was performed, the baby being safely extracted.

The condition of the mother was then highly critical, and the baby had to be revived by artificial respiration. For a week after birth she weighed only five pounds. The mother, despite intense pain and weakness, endeavoured to nurse her, but as progress appeared stationary she was put on alternate feeds of Cow & Gate Full Cream Milk Food and Breast.

From then onwards she made rapid progress and at four months the mother weaned her altogether.

Now eight months old, the child is the picture of contentment and happiness and weighs over 17 pounds.

COW & GATE MILK FOOD

has saved more baby lives than any other preparation in the world

HORMOTONE
for
PREMATURE SENILITY
and
OLD AGE

Stimulates metabolism
Increases muscle tonicity
Raises respiratory exchange
Effects marked subjective improvement

"Old age being caused by degeneration of the endocrine glands, especially the thyroid and sexual glands, all that is necessary to secure rejuvenation is to improve the condition of these glands. The best and easiest way to do this is to administer by the mouth extracts of these glands after their extirpation from healthy animals. . . .

"The persons treated looked considerably younger after it, to the extent of ten or fifteen years, and sometimes even more. The wrinkles in the face already began to disappear four or five weeks after the treatment, and, at the same time, previously corpulent persons, losing their excess of fat, were made to look slender, thus imparting a youthful impression."

(Lorand, "Life Shortening Habits and Rejuvenation," 1922.)

DOSE: 1 or 2 tablets three times daily.

WITH SUPPLEMENT

No. 3666 SATURDAY, APRIL 11, 1931 Price 1/3

THE CONSTIPATION SYNDROME

Whether the symptoms associated with constipation are partly toxaemic or entirely due to neuromuscular disorder, there is no doubt about their reality or their gravely disturbing effect on bodily and mental efficiency.

The influence of emotion, acting through the mediation of the sympathetic nervous system, on bodily processes—markedly on those concerned with alimentation and elimination—is reversible; the psychic consequences of discordant activity of the involuntary muscles being no less striking.

Many vague discomforts and disturbances of health which are often brushed aside as neuroses, or as consequent on undefined focal infections, are, in fact, brought about by disharmonized or ineffective peristalsis.

Thus, we suggest, is explained the undoubted benefit which patients suffering from such disturbances often derive from a morning glass of Eno's "Fruit Salt," taken regularly over a period of a few weeks. In addition to—or by reason of—its purity and its complete freedom from such mineral salts as Epsom and Glauber, Eno is pleasant and refreshing to the palate, as well as effective in action. It has the further merit of being non-habit-forming.

"Urgent Abdominal Diagnostics"

The Proprietors of ENO'S "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "Urgent Abdominal Diagnostics" summarises the salient facts which need to be ever at the front of the mind when faced with an abdominal emergency. The diseased conditions dealt with include those which most often call for immediate surgical attention. It is bound in black morocco limp to conform to the style of the previous publications in this series.

London, W.1.

ENO'S "FRUIT SALT"

B.I. 14

EDWENIL: A POLYVALENT NATURAL ANTIBODY

FOR BACTERIAL INVASIONS OF AN ENDOTOXIC NATURE

in FURUNCULOSIS

Whether there be a single boil or a multiplicity of furuncles, subcutaneous injections of Edwenil will produce a prompt response.

If treated in the early stages, the boil or furuncle disappears without coming to maturity. In more mature lesions the growths quickly come to a head, burst, and there follows a rapid recovery.

The time required for the complete resolving of even an extensive carbuncle is interestingly short.

Similar results have been obtained in long-standing cases of acne, where other forms of treatment, including X-Ray and Ultra-Violet Ray, had failed.

FOR PROMPT RESULTS IN COLDS AND INFLUENZA USE EDWENIL.

Obtainable in 25 c.c. Bottles.

MADE ONLY IN THE LABORATORY OF

E. H. SPICER & CO., LTD.,

WATFORD, HERTS.

Telephones: WATFORD 1784-1785.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

Just Issued

Da COSTA'S Papers and Speeches

Just Issued

The ripened wisdom of a great surgeon, teacher, thinker, lover of books and life is here presented in a new volume which brings together the writings and addresses of Professor J. Chalmers Da Costa. There are papers and speeches, rich with humour and historical facts, on the trials and triumphs of the surgeon, on literary characters, on great physicians and surgeons, living and dead; on old hospitals, old medical schools, old asylums, old books. It is an absorbing, instructive, and entertaining book—delightfully written.

Octavo volume of 440 pages, with portraits. By J. CHALMERS DA COSTA, M.D., LL.D., Samuel D. Gross Professor of Surgery at Jefferson Medical College, Philadelphia.
Cloth, 30s. net.

Andrews' Diseases of the Skin

NEW

"The whole volume is excellently got up, and, considering the amount of matter contained in it, remains moderate in size and easy to handle. We commend it with confidence both to general practitioners and specialists."—BRIT. MED. JOUR.

By GEORGE C. ANDREWS, A.B., M.D., Associate Professor of Dermatology, College of Physicians and Surgeons, Columbia University, etc. Octavo of 1,091 pages, with 988 illustrations. Cloth, 55s. net.

Babcock's Text-Book of Surgery

A STANDARD

"Takes a distinguished place among the many general text-books that are available. It is designed both for the student and the practitioner, as the author believes that, with the increase of clinical teaching and the declining importance of systematic lectures, the student must turn more to his reading for his theoretic background."—BRIT. MED. JOUR.

By W. WAYNE BABCOCK, M.D., Professor of Surgery, Temple University, Philadelphia. Octavo of 1,367 pages, with 1,059 illustrations, 9 in colours. Cloth, 45s. net.

Howell's Text-Book of Physiology

"One of the best, most readable, suggestive, and withal critical of the modern text-books on this subject. Is sound, accurate, philosophical, and thoroughly up to date."—LANCET.

By WILLIAM H. HOWELL, M.D., Ph.D., Professor of Physiology, Johns Hopkins University, Baltimore. Octavo of 1,081 pages. Illustrated. Cloth, 30s. net.

Ford's Text-Book of Bacteriology

"This is one of the most complete single-volume works on bacteriology. It is more than a text-book, as it is described, and constitutes a valuable work of reference with a wealth of detail particularly in systematic bacteriology. . . . The book can be strongly recommended."—EDINBURGH MEDICAL JOURNAL.

By WILLIAM W. FORD, M.D., Professor of Bacteriology, School of Hygiene and Public Health, Johns Hopkins University. Octavo of 1,069 pages, illustrated. Cloth, 37s. 6d. net.

Maximow's Text-Book of Histology

NEW

"The book is one which can be recommended with confidence as a general work of reference for the more advanced student of this branch of study."—BRIT. MED. JOUR.

By ALEXANDER A. MAXIMOW, late Professor of Anatomy, University of Chicago. Completed and edited by WILLIAM BLOOM, Assistant Professor of Anatomy, University of Chicago. Large octavo of 833 pages, with 601 illustrations, some in colours. Cloth, 40s. net.

Ranson's Anatomy of Nervous System

3rd EDITION

"The book provides a useful foundation in macroscopical and microscopical anatomy, considered always with an eye to the physiological correlates of given structures, thus supplying a dynamic as opposed to a static presentation. It is wonderfully complete, and for the novice in neurology it should prove highly serviceable."—LANCET.

By STEPHEN W. RANSON, M.D., Professor of Neurology, Northwestern University Medical School, Chicago. Octavo of 425 pages, with 234 illustrations, some in colours. Third, Revised, Edition. Cloth, 32s. 6d. net.

Herrick's Introduction to Neurology

"One of the most interesting books of its kind, and is easy to read because of the association of anatomy with development and function in a very attractive way."—IRISH JOUR. OF MED. SCIENCE.

By C. JUDSON HERRICK, Ph.D., Professor of Neurology in the University of Chicago. 12mo of 406 pages, illustrated. Fourth Edition. Cloth, 12s. 6d. net.

Todd & Sanford's Clinical Diagnosis

"A book which is of particular value to the student for the number and the excellence of the illustrations, the clarity of the language, and the short, but concise, notes on the indications for the applications of various tests and the interpretation of the results."—LANCET.

By JAMES CAMPBELL TODD, M.D., University of Colorado; and ARTHUR HAWLEY SANFORD, M.D., University of Minnesota (The Mayo Foundation). Octavo of 782 pages, with 318 illustrations, 29 in colours. Sixth (Revised) Edition. Cloth, 28s. net.

W. B. SAUNDERS COMPANY Ltd., 9, Henrietta Street, LONDON, W.C.2

JUST PUBLISHED. 49th YEAR.

With many Text Illustrations and 70 Plain and Coloured Plates. 20/- net.

THE LANCET.—"A reference book used and valued by medical men in every part of the Empire."

Bristol: JOHN WRIGHT & SONS LTD. London: SIMPKIN MARSHALL LTD.

RECENTLY PUBLISHED. FIFTH EDITION. Fully Revised, and Enlarged. Crown 8vo. 1,048 pp. 21s. net; postage 9d.

SYNOPSIS OF MEDICINE

By H. LETHEBY TIDY, M.A., M.D., B.Ch.Oxon., F.R.C.P.Lond.,

Physician, St. Thomas's Hospital; Consulting Physician, Royal Northern Hospital.

"An admirable *index medicus*. . . . The scope is far wider than in the majority of books. Throughout, 'treatment' meets with ample consideration . . . this fact alone will enhance its value enormously for the busy practitioner."—BRIT. MED. JOURN.

"We can say without hesitation that the book is far ahead of any medical synopsis it has been our lot to encounter."—LANCET.

"We have nothing but admiration for this book, and cannot commend it too highly."—MEDICAL PRESS AND CIRCULAR.

Bristol: JOHN WRIGHT & SONS Ltd.

NINTH EDITION. Fully Revised. Crown 8vo. 684 pp. With 163 Illustrations, some of which are coloured. 17s. 6d. net; postage 9d.

SYNOPSIS OF SURGERY

By ERNEST W. HEY GROVES, M.S., M.D., B.Sc.Lond., F.R.C.S.Eng.,

Professor of Surgery, Univ. of Bristol; Surgeon, Bristol General Hospital; Member of the Court of Examiners, Royal College of Surgeons, England; Examiner in Surgery, Universities of London, Liverpool, Leeds, Manchester and Sheffield, and Nat. Univ. of Ireland.

"Complete in its range of subjects . . . among the best of its kind; the author is to be congratulated on its readableness, its lucidity and its fullness—notable qualities."—BRIT. MED. JOURN.

"This synopsis of surgery has had a wide sale, which has necessitated the issue of frequent editions, and it deserves thoroughly all the success it has attained."—LANCET.

THE EXTRA PHARMACOPOEIA

By W. HARRISON MARTINDALE, Ph.D.

Nineteenth Edition.

Vol. I, 27/6 net; postage 6d.
Vol. II, 22/6 net; postage 4d.
Complete Work (2 Volumes) 50/- net, post free.

In Two Volumes.

Vol I (1928) deals chiefly with Treatment, giving the important issues as to CLINICAL USE of all modern CHEMICALS and DRUGS, characters, dosage, methods of prescribing, etc.
Vol. II (1929) COMPLETES THE SET. It is concerned with INVESTIGATIONS, EXPERIMENTAL RESEARCH, DIAGNOSIS, and a large amount of new matter in medicine and allied sciences.

Brit. Med. Journ., Nov. 2nd, 1929, says: "*Has a well-established reputation as a most useful and convenient work of reference.*"
Lancet, Nov. 2nd, 1929, says: "*A clear and authoritative publication of the highest value.*"

Up-to-date Book for everything on the Therapeutic Use of Drugs. It embodies the Latest and Most Varied Information on Chemistry, Pharmacy, Therapy, and numerous other subjects.

MEDICAL PUBLISHERS

1931 PUBLICATIONS — *NEW BOOKS AND NEW EDITIONS*

NEW BOOKS

ABDOMINAL PAIN

(To be published this month)

By JOHN MORLEY, Ch.M., F.R.C.S., Hon. Consulting Surgeon, Ancoats Hospital, Manchester; Hon. Assistant Surgeon, Manchester Royal Infirmary, etc. With an Introduction by Professor J. S. B. STOPFORD, C.B.E., M.D.

Demy 8vo, 208 pp., 22 Illustrations. Price 10s. 6d. net. Postage 6d.

A HANDBOOK OF DISEASES OF CHILDREN

By BRUCE WILLIAMSON, M.D.(Edin.), M.R.C.P.(Lond.), Physician, Royal Northern Hospital; Assistant Physician, Prince of Wales' General Hospital, London.

Crown 8vo, 300 pp. 50 Illustrations and Frontispiece. 10s. 6d. net. Postage 6d.

CHRONIC ARTHRITIS AND RHEUMATOID AFFECTIONS

By B. L. WYATT, M.D., F.A.C.P., Director, The Wyatt Clinic, Tucson, Arizona, etc.

Demy 8vo, 176 pp. Price 15s. net. Post. 6d.

AN INTRODUCTION TO MEDICAL HISTORY AND CASE-TAKING

By GEOFFREY BOURNE, M.D.(Lond.), F.R.C.P., Demonstrator of Practical Medicine and Assistant Physician, St. Bartholomew's Hospital, etc.

Crown 8vo, 200 pp. Illustrated. 6s. net. Postage 5d.

A MANUAL OF TUBERCULOSIS FOR NURSES

By E. ASHWORTH UNDERWOOD, M.A., B.Sc., M.B., D.P.H. (Glas.), Dep. M.O.H. and Tuberculosis Officer, County Borough of Rotherham, etc.

Crown 8vo, 272 pp. 30 Illustrations. 6s. 6d. net. Postage 5d.

NEW EDITIONS

A TEXT-BOOK OF MEDICAL JURISPRUDENCE AND TOXICOLOGY

Adapted as a Text-book by H.M. Government.

By JOHN GLAISTER, M.D., D.P.H.(Camb.), F.R.S.E., Professor of Forensic Medicine, University of Glasgow; in collaboration with JOHN GLAISTER, Jun., D.Sc., M.D.(Glas.), Professor of Forensic Medicine, University of Cairo, etc.

FIFTH EDITION. Demy 8vo, cloth. 970 pp. With 132 Illustrations and 7 Plates. Thoroughly revised. 30s. net. Inland postage 9d. Foreign postage 1s. 6d.

ANTE-NATAL CARE

Including Abnormalities in Pregnancy, with a Section on Post-Natal Care

By W. [illegible] M.B.(Camb.), F.R.C.S.E., Senior Assistan[illegible]nte-Natal Department, Edinburgh Royal [illegible] Memorial Hospital; and E. C[illegible]FALMI F.R.C.S.E., Assistant Obstetric Physicic[illegible] to the same Department and Hospital.

SECOND EDITION. Crown 8vo, 140 pp. Illustrated. 5s. net. Postage 4d.

AN INTRODUCTION TO PRACTICAL BACTERIOLOGY

By T. J. MACKIE, M.D.(Glas.), D.P.H.(Oxford), Professor of Bacteriology, University of Edinburgh; and J. E. M'CARTNEY, M.D., D.Sc.(Edin.), Director of Research and Pathological Services, M.A.B.

THIRD EDITION. Crown 8vo, 440 pp. Illustrated with Diagrams. Price 10s. 6d. net. Postage 6d. (A Guide to Bacteriological Laboratory Work for Students and Practitioners of Medicine.)

PRACTICAL METHODS IN THE DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES

(To be published this month)

By DAVID LEES, M.A., M.B., F.R.C.S., Surgeon in Charge of Venereal Diseases, the Royal Infirmary, Edinburgh; Surgeon in Charge of Venereal Diseases, Royal Maternity Hospital, Edinburgh; Lecturer and Examiner in Venereal Diseases, the University of Edinburgh and the Royal College of Surgeons, Edinburgh.

SECOND EDITION. Crown 8vo, 650 pp. 87 Text Illustrations and 8 pp. of Coloured Plates. 15s. net. Postage 9d.

Would you have sent in this COUPON if you had been living in 1831?

What a stir Frigidaire would have created in those days! And yet, the majority of people are still keeping their food in precisely the same way as in 1831. Isn't it about time we gave great-grandmamma's methods the go-by, and kept our food in the 1931 manner? In the frosty coldness of a Frigidaire food won't "go-off," it stays sweet and fresh, it tastes better because it tastes fresh. Summer time's a week ahead. Why not, in that week, advance 100 years? First step—post the coupon to-night.

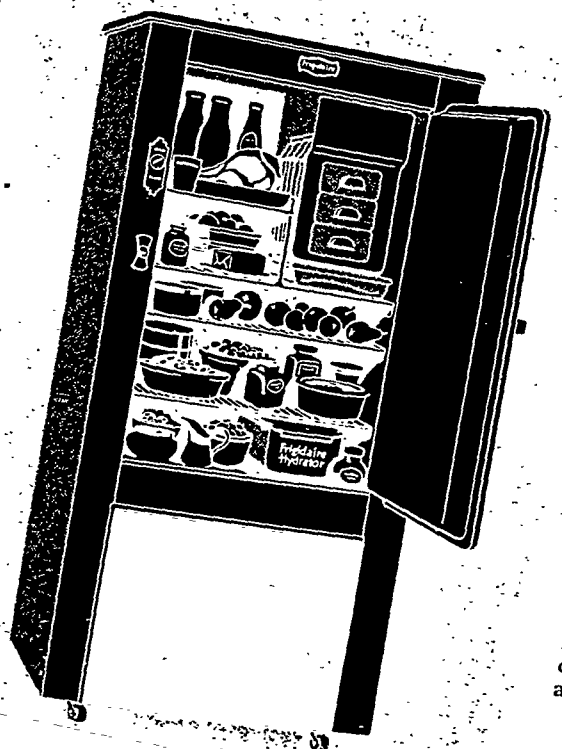
The Quickube Ice Tray, enabling single cubes, or many, or all, to be extracted at once, simply by a light pressure of the finger. No melting them out under the tap. Your cocktail ice is ready at a moment's notice.

•

The Cold Control, by which the freezing of ice cubes or any other frozen delicacy can be accelerated at will.

•

The automatic feature of Frigidaire is invaluable. It cuts out the human element with its forgetfulness and consequent waste. Frigidaire maintains a dry cold that is *always* under 50° — the only safe temperature for food.



Practical flat top, makes a useful shelf.

•

The Hydrator—a *moist* cold compartment, for fresh vegetables, sandwiches, etc. Even wilted vegetables *will* regain their crispness here in a few hours.

•

Ease of installation. A Frigidaire only needs connection with your electric supply. No plumbing is necessary.

•

Frigidaire Cabinets are all white porcelain on steel—the finest durable finish it is possible to have. And *easily* kept clean by *just a rub* with a damp cloth.

•

The new Frigidaire is quiet—you can't hear it start, stop or run.

SHOWROOMS AT 141 NEW BOND STREET, LONDON, W.1, AND IN ALL PRINCIPAL TOWNS.

FRIGIDAIRE LIMITED *(Incorporated in Canada)*

COUPON

Dept. BG-114, Edgware Road, The Hyde, Hendon, N.W.9.

Please give me by return, without any obligation on my part,

(*a*) Price of Frigidaire cabinet suitable to my particular needs as below; or

(*b*) Particulars of your system of convenient deferred payments.

ACTINOTHERAPY

. . . *Really spectacular results on child patients A controlled test*

80% show improvement

ON pages 182 and 183 of "The Lancet" in the issue of January 24th, 1931, appears a new statement of extraordinary interest to all those following the history of light treatment.

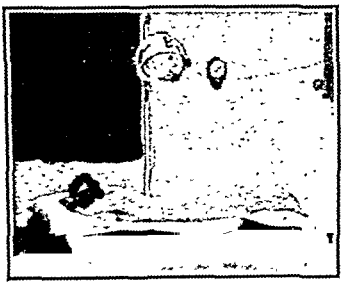
The article brings the question of actinotherapy back to its proper place in medicine—and no one can read it without feeling that it amply justifies the more general use of light treatment in suitable cases.

Every day in your consulting room you must have patients whom you can benefit by means of actinotherapy.

We will gladly send you particulars of the recorded positive results that have been obtained by others. This is information that will cost you nothing; it is the kind of material which (unless you possess already) you can scarcely afford to be without.

If you write to the address below, marking the enquiry Dept. 9, a full list of available free reports will be sent to you together with any other information you may desire.

THE VARIOUS MODELS OF HANOVIA QUARTZ LAMPS



HANOVIA ALPINE SUN for individual treatment.

NERON VITALUX

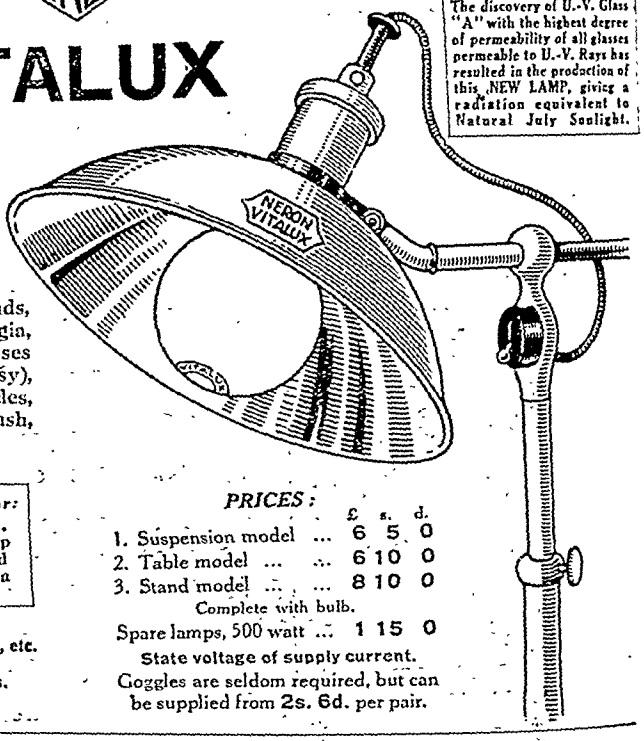
The Sunlight Generator

HEAT, LIGHT, ULTRA-VIOLET

An indication as to some of its uses:

Rachitis prophylaxis, tubercular cervical glands, surgical and cutaneous tuberculosis, neuralgia, rheumatism (neuritis, myalgia), catarrhal diseases (colds), inflammation of the lungs (pleurisy), treatment of wounds, abscesses, furuncles, fungoid diseases of the skin, barber's rash, frontal sinus catarrh.

The discovery of U.-V. Glass "A" with the highest degree of permeability of all glasses permeable to U.-V. Rays has resulted in the production of this NEW LAMP, giving a radiation equivalent to Natural July Sunlight.



Extract from letter recently received from a doctor:
"The lamp is giving me thorough satisfaction, being a great improvement on the carbon arc lamp I was using, owing to the absence of fumes and greater ease of working, as well as giving a more satisfactory spectrum."

Neron Vitalux Lamps are being installed in various hospitals, etc.

Glass prepared free of cost for Hospital Sun Rooms.

PRICES:

	£	s.	d.
1. Suspension model ...	6	5	0
2. Table model	6	10	0
3. Stand model	8	10	0

Complete with bulb.

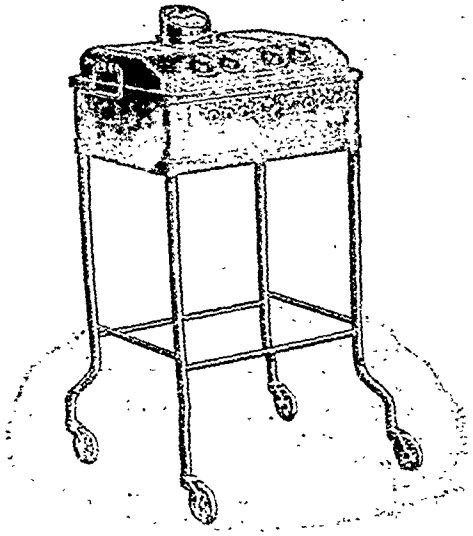
Spare lamps, 500 watt ... 1 15 0

State voltage of supply current.

Goggles are seldom required, but can be supplied from 2s. 6d. per pair.

NEW DIATHERMY APPARATUS

ALL PRICES REDUCED



Machines for purely medical purposes, surgical purposes, and combined models for either purpose.

THERMOFLUX D4

(as illustrated)

This Large Portable Model has a greater output than our well-known C type, viz., 280 watts. Designed to treat up to four patients, or four separate circuits with one patient. Current read in each circuit separately.

Price £47 10 0 Trolly £4. 10 0

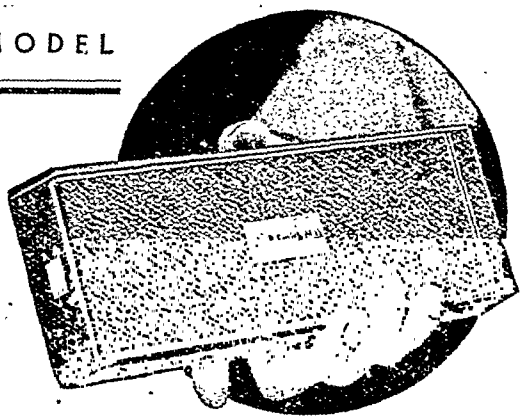
THE NEW KOMPAK MODEL



When the accuracy of any particular diagnostic apparatus is definitely established, its universal acceptance is just a matter of time.

Today, more than one hundred thousand physicians throughout the world are using Baumanometers for determining accurate bloodpressure.

From South Africa to China, from Australia to Canada, physicians have learned from experience to depend upon the scientific accuracy of the Lifetime Baumanometer.

Every Lifetime Baumanometer is a MASTER instrument, individually calibrated, scientifically accurate and guaranteed to remain so. They all carry our exclusive guarantee against glass breakage.

There are four Baumanometer models to choose from, each designed for a specific use, including the new KOMPAK Model—the smallest, the lightest, the handiest, mercurial instrument.

Regardless of the completeness of your bloodpressure apparatus—the KOMPAK Model fills a definite need for a perfect functioning, scientifically accurate, extremely portable instrument.

Note its distinguishing specifications.

Lifetime Baumanometer
STANDARD FOR BLOODPRESSURE

Calibration: 260 mm.
Size: 1⅝" x 3⅞" x 11⅝".
Weight: 30 oz.
Inflation System Self-Contained.
Duralumin case with baked enamel edges.
Genuine Morocco grain leather.
Entire manometer unit chromium plated.
Individual nameplate cast in cover.
Table of clinical averages embossed in case.
Lifetime Guarantee against glass breakage.
Perpetual Guarantee for accuracy.

CAPROKOL

Brand of Hexyl-Resorcinol

The physician looks further than mere palliation. The patient, weary through pain and loss of sleep, asks only for immediate relief.

Caprokol therapy meets the requirements of both.

The gentle analgesic action of Caprokol brings ease and comfort; painful symptoms are abated, hours of unbroken sleep follow, appetite reappears and the patient is grateful.

The physician has the satisfaction of seeing the daily beneficial effects of the action of Caprokol, and the eventual complete disinfection of the urinary tract.

SUAVE AND NON-IRRITANT IN ACTION

These essences supply energy without strain to the digestive system

When the system is in an exhausted condition Brand's Essences of Beef or Chicken stimulate, supply energy and prepare the patient to accept a solid diet.

Scientific tests have proved that these essences reduce the period of digestion by forty minutes and absorbed without the formation of residue.

Recent investigations show that 99 out of every 100 doctors interviewed depend on Brand's Essences of Beef or Chicken in the treatment of specific fevers, in disorders associated with pyrexia, before and after operations, in cases of intestinal disturbances, and in convalescence when the patient's recovery is hampered by anorexia.

The finest freshly killed English meats are used in the preparation of Brand's Essences of Beef or Chicken. By an exclusive process the pure essence is expressed and hygienically conserved in jelly form, easy to swallow and delicious to taste.

On the receipt of a professional card samples will be gladly sent.

Write to Brand & Company, Ltd., Dept. F 30, Mayfair Works, South Lambeth Road, London, S.W.8.

R AND C

Specially indicated in
NEPHRITIS - URÆMIA - ECLAMPSIA - ALBUMINURIA
and allied conditions.

PROMPT and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders. In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary.

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephritin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney, increase urinary secretion, and induce a greater output of urea.

Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated. They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy. The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered.*

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

Dimol

The safest and most reliable non-toxic bactericide for all pathogenic conditions associated with an intestinal focus.

Recommended by the Medical Profession for over ten years. Supplied by the Admiralty for use in His Majesty's Ships and Royal Naval Hospitals.

Dimol Laboratories, Ltd., 40, Ludgate Hill, London, E.C.4.

HORLICK'S MALTED MILK has for many years been advocated as an excellent addition to the diet of the nursing mother, for whom correct dieting should be a matter of the greatest importance. It has been well said that the mother's milk is the baby's birthright. In the early months of life the foundation of baby's future health is laid, and among the many factors which go to the building of this foundation the quality and quantity of the mother's milk are of vital importance. Should the mother's dietary be deficient in any of the important food constituents, her own health and the quality of her milk will be adversely affected and baby will ultimately suffer in consequence. HORLICK'S MALTED MILK, made from full-cream cow's milk and the nutritive extracts of malted barley and wheat, contains all the food elements that the nursing mother needs. It is a well-balanced food, which invigorates and energizes. It stimulates mammary secretion, and ensures that baby's food requirements are adequately fulfilled; it makes the nursing period a joy, and not a time of worry and anxiety.

ACRIFLAVINE (BOOTS)

ONE of the most potent of modern antiseptics, physiologically pure and extremely soluble in water. ACRIFLAVINE (BOOTS) kills organisms in a concentration of 1 in 100,000. Its potency is actually increased in contact with serum. Now recognised as the routine preparation for irrigations in the treatment of Gonorrhœa. Ideal for suppurating wounds and all septic conditions.

Supplied in 5 gm. and 20 gm. bottles, and in Solution Tablets for external use (gr. 1.75 and gr. 2.187).

NEUTRAL - ACRIFLAVINE (BOOTS)

Is specially prepared for internal use (per os) in the form of enteric-coated tablets.

Supplied in 5 gm. and 20 gm. bottles; in Solution Tablets for external use (gr. 1.75), and in enteric-coated tablets (gr. ½) for internal use (per os).

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856.

On the Absorption of Sanatogen

Why it is that Sanatogen is absorbed with ease even by the weakest stomach.

The tonic influence of the glycero-phosphoric-acid in the chemical combination casein-sodium glycerophosphate (Sanatogen) makes the use of casein possible in cases where the patient has to a great extent lost his capacity of absorption (Tunnicliffe, Tischer-Beddies, Chajes, a.o.).

French authorities (Robin and others) ascribe to the glycero-phosphates a great influence on the utilization of the albumin in the body. The manufacture of Sanatogen is conducted under the strictest scientific control ensuring absolute purity, sterility and uniformly high dietetic value.

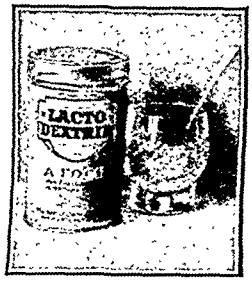
Samples and Literature will gladly be sent on request to:

GENATOSAN LTD., LOUGHBOROUGH, LEICESTERSHIRE.

FAVOURABLE REPORTS *in clinical use of this combination of Lactose and Dextrin*

FURTHER reports have recently been received giving testimony to the value of Lacto-Dextrin as a food for changing the intestinal flora. Lacto-Dextrin is highly efficient in promoting the growth and development of both B. acidophilus and B. bifidus in the colon.

Another important laxative agent for use in conjunction with Lacto-Dextrin is Battle Creek Psylla (psyllium seed). This emollient evacuant supplies both bulk and lubrication and is of special service in fissure and haemorrhoids.



Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, 41, Great Tower Street, London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

VITAMALT

Containing Vitamins A, B and D.

A well-balanced food which ensures an adequate supply of these essential vitamins and which corrects disorders arising from deficiency of these important bodies.

Vitamalt has been skilfully blended to make a preparation which is easily assimilated and provides an acceptable form of vitamin medication.

During expectant and nursing motherhood Vitamalt provides a plentiful supply of vitamins and is a valuable aid to nutrition during this important period.

PITUITARY EXTRACT B.D.H.

(Posterior Lobe)

The presence of both pressor and antidiuretic properties in Pituitary (Posterior Lobe) Extract B.D.H. explains its usefulness in a variety of conditions such as surgical shock, intestina stasis, haemorrhage, the polyuria of diabetes insipidus, in insulin hypoglycaemia, urticaria and angio-neurotic oedema.

The special need for the use of a reliable standardised pituitary preparation is obvious, since different samples of products of this nature often vary considerably in activity.

Pituitary (Posterior Lobe) Extract B.D.H. is a stable solution of uniform potency and efficacy, every batch being tested for oxytocic power and for pressor effect before issue.

ANTIPHLOGISTINE

THE TUBERCULOSIS DANGER!

It has been stated in Parliament that *over two thousand children die every year through tuberculous milk.* How many children who survive grow up weaklings through the taint of bovine tuberculosis? This hardly bears thinking about. Cow & Gate Milk Food is guaranteed absolutely free from tuberculosis and other pathogenic organisms.

Read the following extract from the Presidential Address at the Royal Sanitary Institute Congress at Margate, it is of vital significance to the medical and nursing professions:

'The loss on the agricultural and veterinary side of 52,222 bovines during the three years 1926, 1927, 1928, slaughtered under the Tuberculosis Order of 1925, and at least twice that number not reported but otherwise disposed of, the estimate that 40 per cent. of the cows of our dairy herds producing milk for human consumption are tuberculous, are circumstances in themselves that demand immediate attention. But when to this is added the fact that in England 31.5 per cent. of tuberculosis in children up to 15 years is of bovine origin, and deaths from tuberculosis in children up to 5 years is 29.5 per cent. of bovine origin, that 57 per cent. of cervical adenitis in the same ages is of bovine origin, that 33 per cent. of bone and joint tuberculosis in children under 5 years and 24 per cent. in children from 5 to 10 years is of bovine origin, that in Scotland it is recorded that in certain hospitals in Edinburgh as much as 90.3 per cent. of cervical adenitis and 61.2 per cent. of bone and joint tuberculosis in children up to 12 years is of bovine origin, it is high time that this grave condition and this very serious menace to public health should be mended and ended. It is no credit to us as scientists and protectors of public health that such a state of affairs should be permitted to continue, or even to exist.'

-IS SAFE!

Another remark made at the meeting was as follows:

'It would be better to have no milk supplied at all than to feed children on diseased milk as is being done at present.'

Cow & Gate Milk Food

COW & GATE MILK FOOD

is prepared by our Special Improved Roller Process employing a short heat treatment which destroys all disease organisms but leaves the natural vitamins unimpaired. It is a basic milk food which can be modified by the profession as they desire to suit each and every case.

with the caffein problem in mind—make the Night-Test

Do you have misgivings when you forbid a patient coffee? Do you doubt the patient's ability to say "No" to coffee's tempting fragrance?

With this problem in mind, send the coupon below for a free vacuum-packed tin of H.A.G. Coffee—genuine, delicious coffee, with the effects of caffein minimized. When it arrives, make the night-test—drink your first cup of H.A.G. Coffee at night. Next morning you'll know, from your own experience, that any patient can drink H.A.G. Coffee without danger of caffein effect. More than that—you'll know that the rich, satisfying flavour of H.A.G. Coffee will shield the patient from the temptation to drink caffein-containing coffee.

Real coffee—delicious coffee!

H.A.G. Coffee is real coffee—a superior blend of the choicest Central and South American coffees. The decaffeination process takes place *before* the coffee beans are roasted. This leaves intact all the mellow flavour and fragrance that make coffee "the beloved beverage." Coffee experts recognize that no other blend is finer.

H.A.G. Coffee is under the Independent Control of The Institute of Hygiene and British Analytical Control.

Your grocer stocks H.A.G. Coffee—ground or in the bean and in vacuum tins that preserve its freshness and its fragrance. Or send the coupon below for a liberal sample tin of H.A.G. Coffee. With it we shall be pleased to send a copy of "Some Observations of the Action of Caffein," a more complete discussion of H.A.G. Coffee. Send the coupon now.

The Superiority of Cod Liver Oil as a Cure for Rickets

Leading Authorities have proved by the most painstaking researches that:

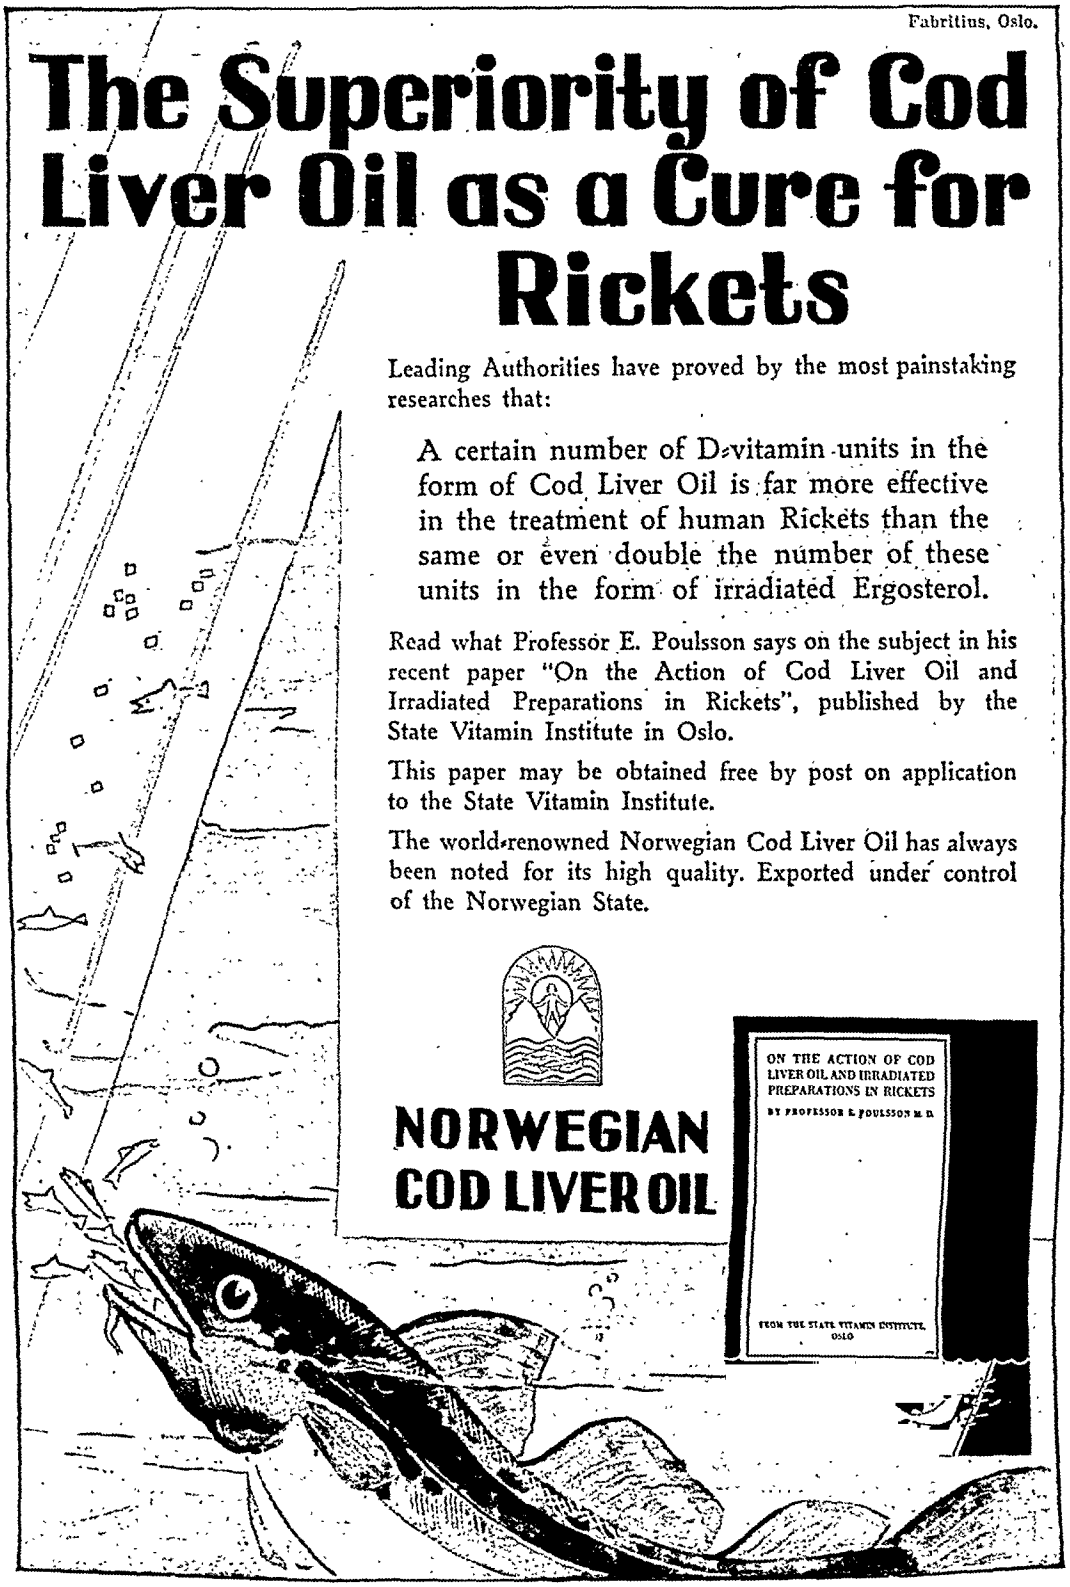
A certain number of D-vitamin units in the form of Cod Liver Oil is far more effective in the treatment of human Rickets than the same or even double the number of these units in the form of irradiated Ergosterol.

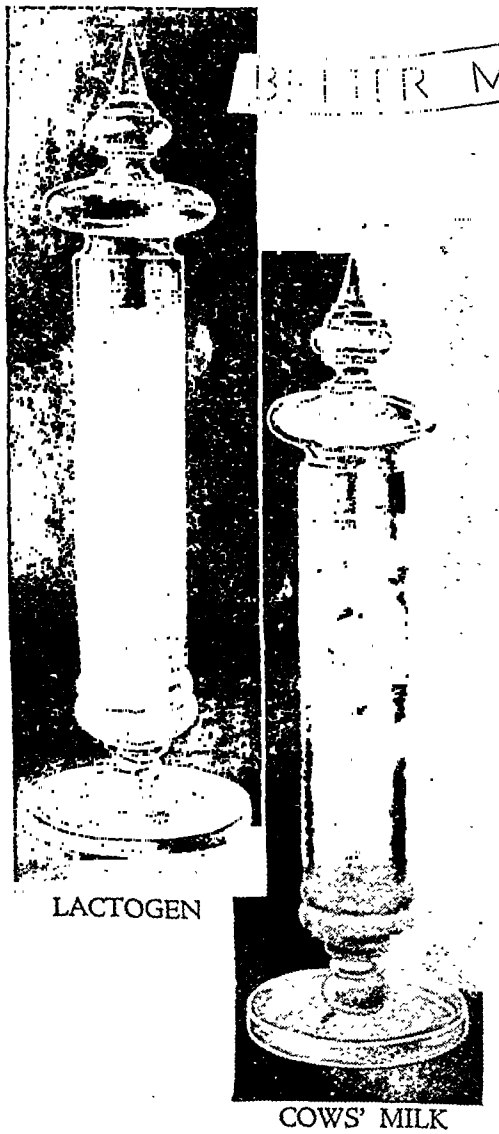
Read what Professor E. Poulsson says on the subject in his recent paper "On the Action of Cod Liver Oil and Irradiated Preparations in Rickets", published by the State Vitamin Institute in Oslo.

This paper may be obtained free by post on application to the State Vitamin Institute.

The world-renowned Norwegian Cod Liver Oil has always been noted for its high quality. Exported under control of the Norwegian State.

NORWEGIAN COD LIVER OIL





LACTOGEN COWS' MILK

FACTS ABOUT
LACTOGEN

Digestibility

*(2) The Protein Content

The digestibility of any milk diet is to a large extent governed by the nature of the curds formed during digestion. The large firm curds of unmodified cows' milk are in marked contrast to those of breast milk, which, being fine and flaky, are easily digested. In the preparation of Lactogen the protein undergoes an essential modification, and the curd formed during digestion is of a finely flocculent nature so characteristic of the natural diet. Lactogen provides a protein allowance comparable with that of maternal milk—in nutritive value and ease of digestion.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

Free Samples
with detailed descriptive literature will be sent to any Member of the Medical Profession upon request.

Introduction to the Medical Profession of

Feen-a-mint

REG. TRADE MARK

The Chewing Laxative

In these days when the number of remedies for constipation is legion, and when almost the whole field of materia medica has been explored, some justification is necessary for bringing yet another laxative to the notice of the Medical Profession.

The laxative is Feen-a-mint, and it carries its own justification—as a trial will readily and most satisfactorily demonstrate.

Feen-a-mint is added to the therapeusis of constipation because it embraces the very desiderata of treatment often lacking in many so-called remedies.

The composition of Feen-a-mint is simple (the active principle being the well-known phenolphthalein) but its *presentation* is a matter of great importance, and one which secures very complete therapeutic results.

In Feen-a-mint, phenolphthalein — in a state of remarkably fine division—is incorporated into a resinous gum base.

This product is intended for thorough mastication by the patient—which further aids sub-division and even distribution on the walls and contents of the intestine, with resulting peristaltic waves—free from griping and without irritation to the intestinal or urinary tracts.

The defæcation from Feen-a-mint is easy and satisfactory, whilst the re-action is the comfort arising from a completely emptied colon.

In a word—Feen-a-mint is the Ideal Laxative because it really ensures evacuation without secondary effects of any kind. It is very agreeable to the palate.

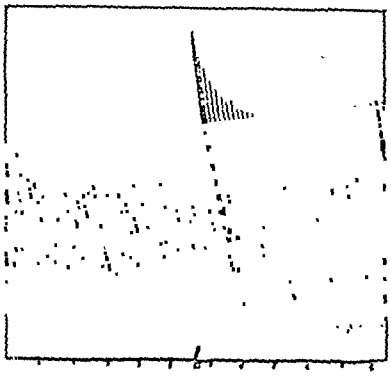
INDICATIONS

CONSTIPATION of all types at all ages. As an eliminant of toxins in pregnancy where other anti-constipative measures have failed.

Prescribing Note :—Feen-a-mint is not therapeutically incompatible with any drug or treatment, and further it is not absorbed.

★ SAMPLE OFFER—*Free of all charge or obligation, clinical samples will be sent on request.*

FEEN-A-MINT PRODUCTS LTD., 1 BUSH HOUSE, LONDON, W.C.2



This tracing was obtained by adding 'DIGINUTIN' to a bath of modified Ringer solution at 37° C., in which a rabbit's auricle was suspended. The time in intervals of two seconds is shown. NINTH PERIOD—circa A.D. 300 to c. 1900

THE EARLIEST EXAMPLE OF LITERARY WRITING IN A GERMANIC TONGUE.—Ulfilas, born and bred among the Goths of the Danube region, became the great missionary bishop to the Goths and sent out other missionaries to the Gothic peoples beyond the Danube. He translated the Scriptures into the vernacular, for which purpose he invented an alphabet. Surviving fragments of his manuscripts are the source of our knowledge of the now lost Gothic speech. (An example is illustrated). Ulfilas has been called "The father of Teutonic literature." A pupil describes him as a man "of most upright conversation, truly a confessor of Christ, a teacher of piety and a preacher of truth; a man whom I am not competent to praise according to his merit, yet altogether keep silence I dare not."

Observations on SOME TENDON RUPTURES*

BY

HARRY PLATT, M.D., M.S., F.R.C.S.

SENIOR HONORARY SURGEON, ANCOATS HOSPITAL, MANCHESTER; LECTURER IN ORTHOPAEDIC SURGERY, UNIVERSITY OF MANCHESTER

Tendon ruptures may be divided into two main groups: (1) The common rupture, produced by the sudden powerful overstretching of a muscle already in a state of contraction. Well-known examples of this type are disinsertion of the extensor tendons of the fingers, and ruptures of the tendo Achillis, rectus femoris, and ligamentum patellae. (2) This comprises a less common and more insidious form of rupture—spontaneous rupture—seen in certain tendons which occupy a bony groove. In these circumstances the rupture is determined by a pre-existing adhesion of the tendon, which gradually becomes attenuated, and ultimately snaps across in response to a comparatively trivial violence. The tendons most liable to rupture by this process of attrition are the extensor longus pollicis and the long head of the biceps. Tendon ruptures may also be classified according to the site of the tear, which may take place (*a*) at the musculo-tendinous junction, (*b*) in the tendon itself, or (*c*) at the point of insertion. Tears in the neighbourhood of the musculo-tendinous junction are almost invariably incomplete, and from a functional standpoint are equivalent to partial tears of the muscle belly—lesions which are usually included under the generic title "strain."

This paper is mainly concerned with the problems of early diagnosis and operative repair in some of the more important complete ruptures. The subject is illustrated by references to typical tendon ruptures selected from my own cases.

Disinsertion of the Extensor Tendons of the Fingers (Mallet Finger)

Avulsion of an extensor communis digitorum tendon is produced by a sudden forced flexion of the terminal phalanx from a blow on the tip of the finger. This injury has been frequently observed in baseball players and in cricketers. It also occurs in a variety of circumstances, and often from what appears to be most inadequate violence. It happens not uncommonly to the housewife or hospital nurse when bed-making. Usually the tendon fibres are completely detached from the margin of the distal phalanx, and may carry with them a tiny wedge-shaped flake of bone (Fig. 1).

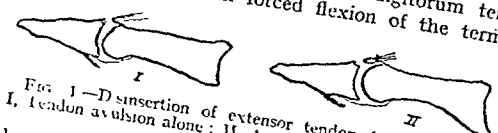

FIG. 1.—Disinsertion of extensor tendon (mallet finger). I, Tendon avulsion alone; II, Avulsion with bony fragment.

Clinical Picture.—The considerable localized swelling which develops in the first twenty-four hours tends to conceal the chief diagnostic sign—the loss of the power of extending the terminal phalanx. For this reason the true state of affairs is frequently overlooked in the early stage. Later, the dropped phalanx and the lack of extension become increasingly apparent, and constitute the typical mallet finger (Fig. 2). The swelling often disappears slowly, and the finger continues to be painful for some weeks. In neglected cases the proximal interphalangeal joint becomes hyperextended and the finger is unsightly and awkward when used.

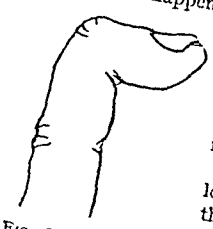

FIG. 2.—Mallet finger; extreme degree.

Treatment.—Excellent results follow the prompt treatment of this injury by prolonged and uninterrupted fixation of the terminal phalanx in a position of hyperextension. A period of not less than four to six weeks is required to ensure sound repair. This fact must be impressed upon the patient, who is apt to regard the accident as a trivial affair. The technique of fixation is most important. A malleable metal splint strapped to the flexor surface of the finger may be used, but offers a strong temptation to the patient to remove it at too early a date. A more effective method is to enclose the whole digit in plaster-of-Paris applied directly to the skin, with a small "sticky felt" pad inserted under the hyperextended terminal phalanx. The proximal interphalangeal joint should be held in a position of very slight flexion in order to counteract the tendency to subluxation with hyperextension (Fig. 3). On removal of the plaster at the end of six weeks, cautious mobilization of the digit is begun, but if the phalanx tends to drop after a few days' treatment, a further period of fixation is necessary. If seen within a few weeks from the date of the accident, a mallet finger should be treated by the method of fixation described above for the full period. Even at this late stage the tendon may become reattached, and reasonable power of active extension of the terminal joint may be regained.

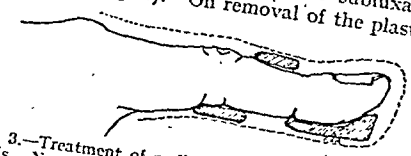

FIG. 3.—Treatment of mallet finger by fixation in plaster-of-Paris. Note position of felt pads.

Repair of the avulsed tendon by operation has been advocated and practised both in the early and in the late stage, but is regarded by most surgeons as an unsatisfactory technical procedure. A comparatively large incision encroaching on the nail bed is needed, and it is difficult to obtain a firm hold for the finest suture material in the fragile end of the tendon and the tissues around the base of the phalanx. In the considerable number of mallet fingers which I have seen and treated, operative repair has been attempted in two cases only. In both, the injury was six weeks old and the result of the operation was disappointing; there was impaired mobility at the terminal joint, with feeble power of active extension of the terminal phalanx.

Biceps Injuries

Proximal Tendons

Rupture of the long head of the biceps is by no means an uncommon injury, but the short head appears to be immune. The long tendon may be torn across: (*a*) in the bicipital groove—extra-articular rupture; or (*b*) may be avulsed from its insertion to the upper margin of the glenoid cavity—intra-articular rupture. The rupture may follow a sudden overstretching, such as occurs during heavy lifting, or may develop insidiously when the tendon has become adherent owing to arthritic changes in the shoulder-joint. Spontaneous rupture is said to occur in elderly subjects quite apart from arthritic changes, and may be preceded by an actual dislocation of the tendon from its groove.[1] When divided by attrition the tendon usually acquires a secondary attachment to the humerus. The majority of spontaneous ruptures have been discovered in the dissecting room, but occasionally the condition is recognized by chance in individuals who give no history of injury.

* Based on a lecture delivered to the Students' Medical Society, Medical School of the University of Leeds, January 27th, 1931.

Symptoms.—The immediate symptoms are typical of tendon ruptures in general. Owing to the depth of the tendon, localized swelling is little marked, and the absence of the tendon when the muscle comes into play may be difficult to demonstrate. Careful testing may show some diminution in the power of flexion of the elbow and supination of the forearm when compared with the opposite side. This injury, like others, is commonly overlooked in the early stage. Later, a flabbiness of the muscle belly, with the bulge nearer the elbow than normal, is the most important sign (Fig. 4).

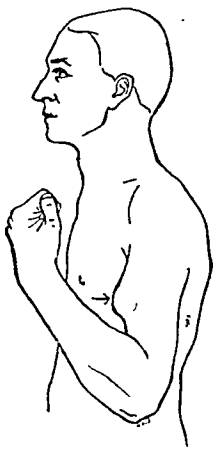

FIG. 4.—Old rupture of long head of biceps. Note bulge and retraction of muscle belly.

Treatment. — When a recent rupture is diagnosed in a man in the prime of life, an attempt should be made to repair the tendon by operation. In avulsion of the tendon from the supraglenoid tubercle, reattachment is likely to be impracticable; but in the bicipital groove end-to-end suture should present little difficulty. When direct repair is impossible the proximal end may be passed through the short head and fixed to the coracoid process.[2] In long-standing ruptures in elderly individuals operation is rarely worth while.

My series of operations for complete tendon ruptures includes no example of rupture of the long head of the biceps.

Distal Tendon

Rupture of the biceps tendon of insertion at the elbow is an exceedingly rare injury. I can find no record of this lesion in surgical literature. Three years ago I had the unusual experience of operating on a patient who, some forty-eight hours previously, had sustained a complete avulsion of the tendon from the bicipital tubercle.

CASE 1

A male, aged 44, while handling a model gear-wheel, stepped back suddenly to prevent the wheel falling on him. Soon afterwards the left elbow became very swollen and painful, and a definite weakness in the power of flexion of this joint was noted. When examined twenty-four hours later there was marked swelling and bruising in the left ante-cubital fossa. The biceps belly was soft and flabby, and retracted to a higher level. When the elbow was actively flexed the muscle was obviously out of action and the distal tendon could not be felt. Operation was advised and accepted.

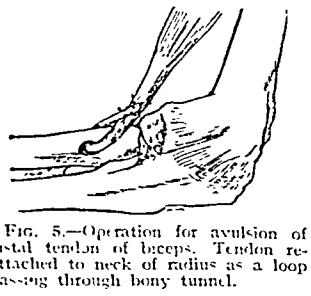

FIG. 5.—Operation for avulsion of distal tendon of biceps. Tendon re-attached to neck of radius as a loop passing through bony tunnel.

An incision was made along the line of the biceps in the ante-cubital fossa and a considerable haematoma evacuated. There was no trace of the bicipital fascia, which had evidently been completely torn across. The tendon was discovered lying curled up like a snake, with its free end slightly oedematous and rounded. The neck of the radius was then exposed, after retracting the brachial artery and median nerve to the inner side and the musculo-spiral nerve to the outer side. The bicipital tubercle was seen to be quite bare: there remained no trace of any fibres of insertion to which the avulsed tendon could be reattached. The tendon was therefore passed through a tunnel drilled transversely in the neck of the radius, and on emergence was sutured to itself under fair tension, with the elbow in the position of right-angle flexion (Fig. 5). After closure of the wound, the arm was fixed in this position in a light plaster-of-Paris cast. Faradic stimulation of the biceps was begun ten days later, and at the end of a fortnight gentle active movements of the elbow were encouraged. Six months later the biceps muscle was acting with full power; a strong tendon could be felt in the ante-cubital fossa, and there was a complete range of movement at the elbow-joint.

RUPTURE OF THE EXTENSOR LONGUS POLLICIS

Rupture of the long extensor of the thumb in the radial groove (Fig. 6) is the best known of the spontaneous tendon ruptures, and numerous examples have been recorded in the surgical literature of various countries.[3] The condition occurs either as an isolated lesion or as a sequel of fracture of the lower end of the radius. The former type was probably first recognized and described

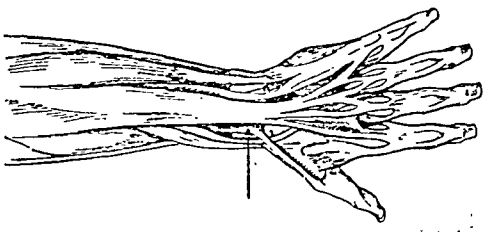

FIG. 6.—Extensor longus pollicis. Site of rupture in bony groove.

many years ago by German military surgeons under t title "kettle-drummer's palsy" (von Zander). In t drummer the rupture has most frequently been seen the left hand, and is generally preceded by a painf tenosynovitis caused by the prolonged use of the dru stick. When the lesion is associated with fracture, t tendon rupture takes place some weeks after the occu rence of the bony injury. The sequence is fracture, di tortion of the tendon groove, adherence of the tendo gradual attrition, rupture. Seven cases have come und my personal observation during the past three year one was that of a weaver in whom the rupture follow an occupational tenosynovitis; the remaining six ca were all associated with fracture of the lower end of t radius. In four cases, the tendon was repaired by ope tion; three patients declined to submit to operation.

CASE 2

Bricklayer, aged 23. Fracture of the lower end of t right radius with very little displacement; returned to wo seven weeks later; worked for five weeks; gave up wo owing to weakness in the thumb and inability to gra bricks. When examined nine months later, extensor long pollicis out of action. The operation of end-to-end sutu was performed. Tendon in groove represented by a f strands of scar tissue. Ends trimmed and approximat under tension; suture reinforced by a fine strip of fas lata. Repaired tendon not replaced in the groove; oblic course not preserved. The result was fair function, but was marred by late stretching of repaired tendon, and by l of obliquity.

CASE 3

Male, aged 50. Colles's fracture with very slight displ ment; five weeks later he felt something snap in his thu while putting on a glove. Examined twenty-four ho later, extensor longus pollicis tendon out of action. Sut was done ten days after rupture. No trace of tendon groove; considerable retraction of ends. End-to-end sutu oblique course preserved. Perfect restoration of func resulted.

CASE 4

Male, aged 18. Subperiosteal fracture of lower end radius with no displacement; perfect function seen a three weeks; worked for eight weeks, then noticed inabi

to straighten the end of the thumb. Examined eleven weeks after rupture, extensor longus pollicis tendon out of action. Tendon in groove intact and not adherent; below groove, tendon showed a fusiform expansion, and was obviously elongated. Resection of fusiform swelling; end-to-end suture. Function was perfectly restored.

Probably this was an incomplete rupture which had healed, leaving an elongated tendon.

CASE 5

Colles's fracture in a female, aged 19, united with considerable deformity; fair functional result. One year later patient found herself unable to straighten the end joint of the thumb. No history of any fresh injury or of preceding discomfort. Examination showed extensor longus pollicis tendon out of action. At operation there was no trace of tendon in groove, which was much distorted; owing to size of the gap, end-to-end suture impracticable. Gap closed by free tendon graft (from extensor longus digitorum of the foot); oblique course preserved by passing tendon through fascial pulley (Fig. 7). Perfect result.

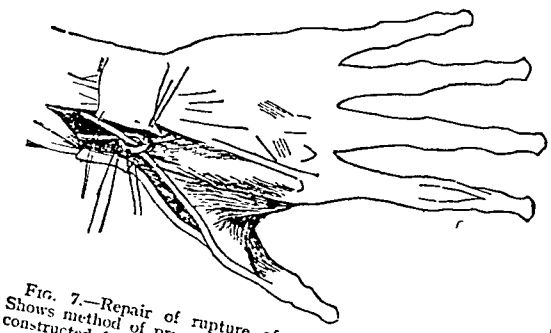

FIG. 7.—Repair of rupture of extensor longus pollicis. Shows method of preserving obliquity of tendon by pulley constructed from fascia.

Diagnosis.—The diagnosis of rupture of the extensor longus pollicis rests on two signs: (1) inability to extend the dropped terminal phalanx of the thumb against resistance; (2) absence of the subcutaneous bowstring normally formed by the tendon when the thumb is fully extended. It is sometimes possible to feel the distal part of the divided tendon and to demonstrate its unusual laxity. The loss of function may also be demonstrated by stimulating the muscle belly by the faradic current. When the distal end acquires a stout adherence to the lower end of the radial groove, dropping of the proximal phalanx is often inconspicuous.

Treatment.—Repair by operation should be undertaken without delay. In a recent rupture, before wide retraction of the ends has taken place, direct suture is usually feasible. In order to secure perfect function the oblique course of the tendon should be preserved, but if the bony groove is much distorted, or the localized scarring is considerable, the original bed is unsuitable for a newly repaired tendon. The construction of a pulley from a free fascial graft, as used successfully in Case 5, is a method of overcoming this difficulty (Fig. 7). In older ruptures, where a considerable gap remains to be closed, direct suture is also the method of choice, but if impracticable, a free tendon graft should be inserted. Alternatively, the distal end of the tendon may be attached to one of the short thumb tendons, a procedure which cannot restore independent action in the long extensor, but which prevents the dropping of the terminal phalanx. After any form of operative repair the thumb should be supported in full extension for three weeks. Early function should be encouraged from the seventh day onwards by faradic stimulation of the muscle belly in the forearm.

RUPTURE OF FLEXOR PROFUNDUS DIGITORUM

My series contains a single example of a rare tendon injury—rupture of one of the long flexor tendons of the fingers.

CASE 6

Rupture of flexor profundus digitorum of left ring finger in a male, aged 16. Swelling in palm of left hand after playing Rugby football. Played two or three games during the next few weeks without much difficulty, but was aware that he could not bend the end joint of the ring finger. Examination two months after "injury" disclosed a localized swelling in the left palm in long axis of metacarpal of ring finger; complete inability to flex terminal phalanx of this digit. The common flexor sheath of the ring finger was opened in the palm; proximal end of ruptured profundus tendon swollen and rounded; no trace of distal end. Skin incision prolonged along finger; distal portion of tendon identified, consisting of thin strand extending from site of bifurcation of the sublimis tendon to point of insertion; obviously unsuitable for use in direct repair. Gap could not be closed by direct suture. Free tendon graft from palmaris longus sutured to proximal end of profundus tendon, and sutured to the remains of profundus tendon in the region of its insertion. After-treatment consisted of faradic stimulation of the muscle through normal split in the sublimis, and sutured to the belly in forearm begun on the fifth day. The result was restoration of fair power of flexion of the terminal phalanx.

This case illustrates (*a*) the considerable retraction of the proximal end which occurs in rupture of a flexor tendon; (*b*) the rapid degeneration of the distal end within a few weeks after the rupture; (*c*) the restoration of continuity by a free tendon graft.

TENDO ACHILLIS

Rupture of the tendo Achillis is essentially an injury of middle life, and may be produced in many diverse circumstances. The clinical picture has been familiar for centuries, and accurate descriptions can be found in the writings of Ambroise Paré, J. L. Petit (1721), and the Edinburgh anatomist and surgeon Monro (1781), who, like John Hunter, was himself a victim of this accident.

Although incomplete ruptures of the Achilles tendon occur, they are admittedly rare, except in the region of the musculo-tendinous junction, where the lesion is popularly but incorrectly described as rupture of the plantaris. It is believed that an incomplete tear in the lower part of the Achilles tendon may be converted into a complete rupture by a second injury a few days or weeks later—the rupture "en deux temps" of the French writers Quénu and Stoianovitch.[4] In the ordinary complete rupture the tendon gives way through its narrowest part about one and a half inches above its insertion. The rupture may be represented by a clean transverse section, or the tendon bundles may break at different levels, leaving ragged and "skein-like" ends. The sheath may be uninjured, but more frequently there is a localized tear. The sheath remains intact on the posterior aspect. Immediately following the rupture the proximal end retracts owing to the pull of the powerful calf muscle. The interior of the sheath rapidly fills with blood, and the walls of the sheath become oedematous. It is a striking fact that the plantaris tendon almost invariably remains intact (Fig. 8).

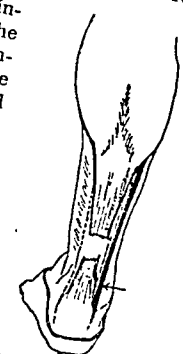

FIG. 8.—Complete rupture of tendo Achillis. Note that plantaris remains intact.

Clinical Picture.—At the moment of rupture the patient experiences a sudden pain, sharp and stabbing, as if from a direct blow over the tendon. The immediate disability is usually considerable, and in a short time the injured region becomes swollen and tender. If a complete

rupture of the tendo Achillis is overlooked, and the unfortunate patent is encouraged to walk about, the whole foot becomes swollen and painful. At a later stage the sheath and the swollen proximal and distal ends of the tendon are often exquisitely tender. In untreated ruptures the thickened sheath becomes adherent to the tendon ends, and acts as a feeble bond of union. The calf muscle remains elongated, and the power of plantar flexion is permanently impaired.

Diagnosis.—The diagnosis of complete rupture of the tendo Achillis is not always a simple matter, and particularly when the leg is examined twenty - four hours after the accident. The intact plantaris tendon, and the distended and oedematous sheath, mask the gap and give an impression of unbroken continuity. It is thus not surprising that complete rupture of the tendo Achillis frequently escapes diagnosis. A careful scrutiny, however, should establish the existence of the following signs: (1) A gap into which at least one finger can be introduced, and which is increased by dorsiflexing the foot. (2) High retraction of the calf belly. (3) An abnormal range of passive dorsiflexion when compared with the uninjured side (Fig. 9). This is perhaps the most important diagnostic sign of all; it is absent in partial ruptures. (4) The loss of true gastrocnemius and soleus action in plantar flexion, a movement still carried out with fair vigour by a combination of the peroneus longus, tibialis posticus, and long flexors of the toes. The break in continuity in the tendon may also be demonstrated in a lateral radiogram taken with a soft tube, a useful method of examination which should not be omitted in doubtful cases.

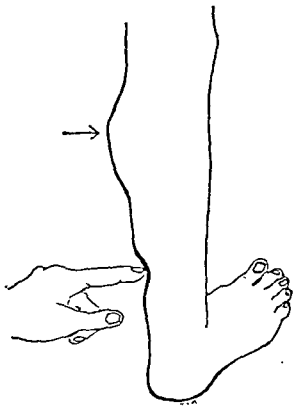

FIG. 9.—Complete rupture of tendo Achillis. Note (*a*) gap; (*b*) high retraction of calf; (*c*) abnormal range of dorsiflexion at ankle-joint.

Treatment.—Recent complete ruptures should be repaired by operation as soon as possible. After opening the tendon sheath and evacuating the contained clot traction is applied to the proximal end of the divided tendon. With the calf fully relaxed by plantar-flexing the ankle and flexing the knee, the ends can be approximated without undue tension. Contact is best maintained by a stout transfixion suture of kangaroo tendon inserted transversely well above and below the line of rupture. Additional security is provided by a number of catgut stitches of lesser calibre. Absorbable suture material is as a rule preferable, and more especially when there is much induration of the tendon ends. In the sliding tears with ragged bundles there is a tendency for the sutures to cut out. In such circumstances the site of union should be reinforced by a living suture fashioned from a strip of fascia lata. The sheath should be carefully restored whenever practicable. At the completion of the operation the leg is fixed in plaster-of-Paris, with the foot in full plantar flexion and the knee in flexion. Three weeks later the foot is brought gently to the right-angle position, and a plaster applied, in which the patient is allowed to walk. Six weeks from the time of the operation the plaster is removed, and walking allowed in a slipper with an elevated heel. Massage, faradic stimulation of the calf muscle, and graduated exercises follow, with re-education in the normal heel-and-toe gait. The ultimate results of suture of the tendo Achillis in recent ruptures are eminently satisfactory. If for any reason operation is contraindicated, the foot should be fixed in full equinus for six weeks in the hope that a fibrous tissue bridge may form in the gap.

In old, neglected ruptures seen a few weeks or even months after the injury, the great retraction of the calf, the fibrous infiltration of the tendon ends—which now require trimming—and the adhesion of the sheath, are factors which enhance the difficulty of operative repair. In order to obtain even bare contact of the divided ends it is necessary to mobilize the proximal part of the tendon and gastrocnemius belly for a considerable distance, and to apply powerful traction with the knee flexed. In my judgement, reinforcement of the suture line by a strong fascial strip is essential in all late repairs. The plantaris tendon may also be used as a reinforcement (see Case 15). In exceptional ruptures where the gap cannot be closed by direct suture, either the turning down of a flap or the insertion of a free tendon graft must be contemplated; procedures which restore continuity at the expense of a permanently lengthened calf. Of the two alternatives, in my opinion, the graft is to be preferred, as the fibrosed avascular proximal end of the Achilles tendon is most unsuitable material for a living bridge. If a graft is used it may be wise to strengthen the power of plantar flexion by transplanting the peroneus longus and tibialis posticus to the os calcis at the site of the Achilles insertion (Case 9).

Case Records of Complete Ruptures of Tendo Achillis

Case	Sex, Age, etc.	Accident	Operation	Result
7	F., 43 Left	Tennis. Undiagnosed for several weeks	Tendon grafting (3 months [illegible] ends ragged	Good function; [illegible]
8	M., 42 Left	Tennis		
9	F., 26 Left	Jumping a vaulting horse. Undiagnosed for 6 months	Tendon grafting + transplantation peroneus longus and tibialis posticus to os calcis (6 months after injury). Plantaris intact	Perfect function; plays all games
10	M., 45 Left	Badminton	Suture, with fascial reinforcement (5 days after injury). Plantaris intact	Perfect function
11	M., 49 Right	Badminton	Suture (2 days after injury); fascial reinforcement. Plantaris intact	Perfect function
12	M., 40 Left	Tripped over a stone	Suture; fascial reinforcement (5 weeks after injury). Plantaris intact	Perfect function
13	M., 60 Left	Turning round suddenly, twisted left ankle	Suture (2 weeks after injury). Plantaris intact	Perfect function
14	M., 58 Left	Slipped on deck of liner	Suture (9 weeks after injury); reinforcement by flap and fascial strip. Plantaris intact	Perfect function; has since climbed Matterhorn
15	M., 54 Right	Caught foot in a hole in the floor. Undiagnosed for some weeks	Suture (9 weeks after injury); reinforcement by plantaris	Perfect function
16	M., 38 Right	1. High diving; pain back of calf 2. Nine weeks later, strained right ankle; felt similar pain	Suture (12 weeks after injury); fascial reinforcement. Plantaris intact	Excellent function six months later; further improvement anticipated
17	M., 41 Left	1. Jumping on sandy beach; (?) rupture of tendo Achillis 2. Four weeks later walking up steps felt something snap above heel	Suture (6 weeks after injury). Plantaris intact	Perfect function

RECTUS FEMORIS

The strong rectus femoris tendon may be torn across during a powerful muscular contraction as an alternative to the more familiar injury, fracture of the patella. The mass of tendon fibres are usually avulsed from the upper [illegible] slender deep

strip may remain intact. The suprapatellar pouch of the knee-joint is torn and a haemarthrosis develops. The victims of this injury are almost invariably past middle age, and the clinical picture is typical of tendon ruptures in general. The gap in the line of the tendon is usually obvious, and in spite of the integrity of the vastus externus and internus, the power of active extension of the knee is completely lost. My own operative experience of this injury comprises three cases only—in vigorous men 72, 58, and 68 years of age respectively—and in each instance the result was complete restoration of function.

Cases of Rupture of Rectus Femoris

Case	Sex, Age, etc.	Accident	Operation	After-treatment
18	M., 72 Left	Slipped and fell on icy footpath	Suture (1 week after injury); slender deep strip intact	Faradic stimulation of quadriceps after tenth day. Active mobilization after 3 weeks
19	M., 58 Left	Slipped with leg underneath him	Suture (3 days after injury)	As above
20	M., 68 Left	Slipped while walking downstairs	Suture (4 days after injury); deep strip intact	As above

LIGAMENTUM PATELLAE

Rupture of the ligamentum patellae is the least common injury of the knee extensor mechanism. The upward retraction of the patella, the absence of the ligament, and the loss of power of extension of the knee are the obvious diagnostic signs. In a recent rupture direct suture should always be feasible. In a long-standing untreated rupture, where there is marked retraction of the quadriceps and patella, and the ligament is represented by an attenuated fibrous band, the construction of a new ligament is necessary. The technique of such an atypical procedure is illustrated in the two examples of this injury in my series.

CASE 21

Male, aged 50. Complete rupture of left ligamentum patellae, sustained six months previously. Operation was done to reconstruct ligamentum patellae by free fascial graft. Tibial crest in the region of the tubercle drilled transversely; long strip of fascia lata removed from the thigh, carried through the drill hole, and free ends sutured to each other and remains of ligamentous tissue at apex of patella. The after-treatment consisted of fixation on Thomas's splint for three weeks, faradic stimulation of the quadriceps muscle after the tenth day; cautious mobilization of the knee-joint after four weeks. Four months later the patient could actively extend the knee from the position of 60 degrees flexion, and the reconstructed ligament could be felt as a stout band. Patient was lost sight of for some months; when examined nine months from the time of operation it was discovered that the ligament had stretched and the power of extension had become feeble. Further operative treatment advised, but refused.

CASE 22

Rupture of left ligamentum patellae in a male, aged 44, eight weeks previously. Notes of operation: Free ends of (*a*) long strip of fascia lata, and (*b*) semitendinosus tendon (both still attached at their lower ends) passed in opposite directions through tunnel in apex of patella. Fascia lata strip long enough to be brought down to tibial tubercle and carried through tunnel in tibial crest at this level, where it was stitched to itself, to neighbouring periosteum, and remains of the ligamentum patellae. Semitendinosus tendon not long enough to reach tibial tubercle; free end stitched to the fascia lata strip between the patella and tubercle. It was noted at the operation that there was no trace of either the ligamentum patellae or the fascial expansion from the vasti muscles; the lower end of the femur was covered by a thin capsule only. After-treatment was carried out by fixation on Thomas's splint; faradic stimulation of the quadriceps after the tenth day; walking allowed after the third week in a posterior shell; active mobilization of the knee begun after the fourth week. The result was a strong tendon, but permanent elongation of extensor mechanism; fair power of active extension, but range of flexion remains limited to 60 degrees.

I am indebted to my colleague Dr. Margaret H. Morley for the accompanying illustrations.

MINERS' NYSTAGMUS

BY

W. E. COOKE, M.D., F.R.C.P.ED., D.P.H.

DIRECTOR OF THE PATHOLOGICAL DEPARTMENT, WIGAN INFIRMARY

Miners' nystagmus is an occupational disease peculiar to workers in coal mines in which the illumination is deficient. The nystagmus is fine and rapid, rotatory, pendular, and vertical. Violent rotatory movements of the eyeballs may be present and continuous with the eyes at rest, if such a state be possible, while in other cases the nystagmus is latent, is difficult to elicit, and is transitory. The movements are equal in frequency and range in both eyes, and are most commonly actuated by looking upwards with the head fixed.

The generally accepted theory of causation is that in dim light the retina functions by means of the rods and not the cones. There are no rods at the fovea centralis, so that in a bad light the eye must move 15 degrees or more from its midpoint to obtain the image of an object. Irregular reflections from the uneven coal surface and the constant maximum stress on accommodation contribute to the general eyestrain.

In some respects miners' nystagmus resembles the occupational palsies. It manifests itself only after a long period of work at the coal face, just as the craft palsies affect the expert and not the novice, and there is loss of volitional control of some of the extrinsic eye muscles. The condition is often accompanied by spasm of the levator palpebrae muscle, and by blepharospasm, and the frequent presence of neuroses further illustrates the resemblance. In the occupational palsies, however, the spasm affects muscles directly concerned; in miners' nystagmus the muscles affected by spasm are some distance away from those directly implicated, and the spasm bears no relationship to the severity of the condition. In fact, severe blepharospasm is often present when nystagmus cannot be elicited by any means, and violent nystagmus may be present without blepharospasm. The spasm in this respect resembles a reflex spasm, and in certain cases a psychasthenic tic.

There are also several points of resemblance between miners' nystagmus and tetany. The constant positional changes due to the dim light lead to exhaustion and hyperexcitability of the myoneural apparatus of the extrinsic eye muscles. This corresponds to the local tetanies from fatigue. Like tetany, nystagmus may be latent, and become apparent only when tension is placed upon the muscles by the patient looking upwards with the head flexed and fixed. In many cases nystagmus is exhibited only when the patient has been in a stooping position for some time and then looks upwards, with the

head fixed ; in others the condition is seen only when the patient is actually stooping. Analogies may be drawn between the sudden tension caused by looking upwards with the head flexed and fixed and Chvostek's mechanical stimulus, and the stooping posture and Trousseau's congestive sign in tetany.

In a consideration of the pathogenesis of the condition three further points must be mentioned. Latent nystagmus may become evident under a variety of conditions. During the early stages of chloroform or ether anaesthesia, before the operation has commenced, unsuspected nystagmus may become marked. When the patient has recovered from the anaesthetic the nystagmus may disappear completely or may persist. This remark applies to acute alcohol poisoning in a nystagmus patient. Secondly, acute infections, such as influenza, tonsillitis, otitis media, antrum infection, pneumonia, and septic wounds not infrequently turn a latent into an active nystagmus. The third precipitating cause is well known. Any accident, from a fractured femur to a simple bruise, may result in nystagmus becoming evident and persisting. The reason of this is probably explained by the experimental results of Danzer[1] on the effects of tissue injury *in vivo*. Danzer found that the active substance to marrow stimulation on injecting extracts of organs was the contained protein, which from the intense marrow reaction caused must be regarded as a toxic stimulus. It was also found that the fracture of bones and the crushing of muscles acted in exactly the same manner. But from the length of time (five hours) required for the commencement of the reaction, compared with the rapid action (two hours) of such substances as nucleic acid, the stimulating substance is considered to be a protein fraction. A similar action probably occurs where there is injury in a case of latent nystagmus. The liberation and splitting up of protein caused by accident results in the absorption of a toxic substance, which, in addition to its general effect, has a local effect on the already impaired myoneural function of the eye muscles.

Everyone agrees that defective illumination is the primary cause of miners' nystagmus, but if bad lighting were the sole cause one would expect the disease to be even more prevalent than the highest figures quoted below. From the behaviour of nystagmus under the conditions just mentioned it is a reasonable assumption that there exists a precipitating factor which transforms a latent condition into an active nystagmus, and which is probably the accessory to deficient illumination in the production of the latent case. The present investigation is an attempt to isolate this factor.

INCIDENCE OF NYSTAGMUS

The incidence of nystagmus among underground workers has been estimated at from 5 to 35 per cent. Of 27,982 underground workers, Nieden[2] reported that 5 per cent. had nystagmus ; Dransart and Famechon[3] gave 10 per cent., and Libert[4] 23.9 per cent. In a systematic examination of 173 colliery officials, mostly firemen, employed at eleven separate collieries, Llewellyn[5] noted " latent nystagmus " in 35.2 per cent., and Court[6] found 34.75 per cent. of all coal cutters affected.

All workers in coal mines are not under the same conditions. The workers at the coal face are in a position of strain for long periods, and are subjected more than others to a constant change of position of the eyes in consequence of the dim light ; it is they who have to use their powers of accommodation excessively. The incidence of nystagmus is far greater among workers at the coal face than among other mine workers.

The number of workers " affected by " nystagmus has little relation to the number who discontinue work owing to the disease and who are certified as " suffering from " nystagmus. The percentage ceasing work and certified as suffering from nystagmus is from 0.05 to 0.5 per cent. It is important to bear these figures in mind, because any theory must account not only for the incapacitated few but also for the large number affected.

RESULTS OF INVESTIGATION

Fifty-seven miners who had been certified and who had ceased work because of the disease were examined. At the time of examination some were still unfit for work, others were working on the surface, and one or two in the mine. The cases were voluntary, and were not consecutive either in dates of onset or in the dates of certification. Serious objection could be taken if this were a statistical review, but as a method of sampling for the purpose of eliminating non-material facts and of forming a starting-point for further investigations the procedure could not be improved. It must be remembered that these cases were taken from the 0.5 per cent. group (the certified group) ; no case of the larger " affected " group was included.

Each investigation and test was followed up in a series of cases until conclusive proof was forthcoming that any variations from the normal could not be a common factor. It was early apparent that the age of onset, the colour of the eyes, the period worked in the mine or at the coal face, and the height of the coal seam could be dismissed. The use of the oil safety-lamp was a common factor, but we already knew that such poor illuminants were the primary cause. Careful inquiries into the family histories and familial and hereditary predisposition to miners' nystagmus yielded negative results, and no frequently recurring factor was found in the past histories. Diet also proved an unprofitable field. The diets varied from the strictly vegetarian to the large meat diet without fruit or green vegetables. The consumption of alcohol and tobacco also varied from total abstinence from both, abstinence from one or the other, to indulgence in both. Errors of refraction were not so frequent as to be a common factor. Examination of the central nervous system, the circulatory, respiratory, and renal systems was also negative for our purpose.

Examination of the Blood

Syphilis was promptly ruled out by negative Wassermann reactions. The calcium content test of the serum and the " available " calcium test of Lee and Vincent were normal in a sufficient number of cases to exclude gross alteration in the calcium level.

No constant defect in the functional activity of the thrombocytes, as indicated by the bleeding time, was detected, nor was there any abnormality often present in the coagulation time or in the retraction of the clot.

Frequent but inconstant deficiencies were found in the percentage of haemoglobin and in the total erythrocyte count. The total leucocytes showed variations from 12,000 per c.mm. to 4,000 per c.mm. Although the differential counts did not show any constant abnormality, there were two interesting features. The first was a definite increase in the percentage of monocytes, the average being 8.9 per cent. ; the second was the almost constant presence of basophils and the unusually frequent appearance of plasma cells in the blood films. The average figures of the differential count were as follows: neutrophil polymorphs 61.7 per cent. ; lymphocytes, 27.2 per cent. ; monocytes 8.9 per cent. ; eosinophils, 1.1 per cent. ; basophils, 0.8 per cent. ; and plasma cells, 0.24 per cent.

Polynuclear Count.—On completion of the series it was seen that not one case had a normal Arneth count. Although allowance was made for the fact that the majority of the cases were examined in the winter and spring, when catarrhal infections are common, the constant gross

abnormal counts required further investigation. The normal polynuclear count may be taken to be:

I	II	III	IV	V
10	25	47	16	2

The weighted mean of this count is 2.75. The maximum and minimum variations in the counts of fifty-seven normal persons as compared with the corresponding number of nystagmus patients were 3.05 and 2.48 respectively. The average polynuclear count in the nystagmus cases was:

I	II	III	IV	V
30	39	27	4	0

This gives a weighted mean of 2.02. The maximum and minimum variations in these cases were 2.39 and 1.70 respectively These differences will be better appreciated by the frequency polygons of the two groups (see diagram).

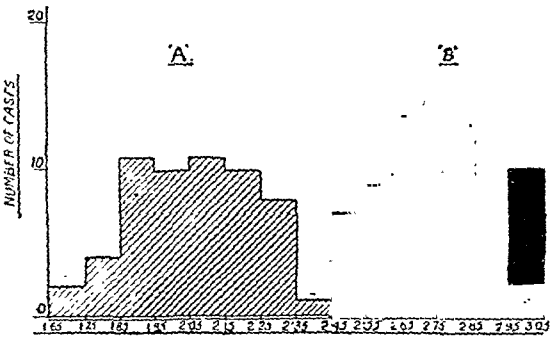

Diagram showing frequency polygons of the polynuclear counts; "A," fifty-seven nystagmus cases; and "B," fifty-seven normal persons. Weighted means grouped in intervals of 0.1.

Frequency Polygons

The Arneth count is altered in a variety of conditions and by many different agents,[3] and although it is possible to take fifty-seven apparently healthy people and not find one count to conform with Arneth's figures or the normal figures quoted above (unless the cases were followed up and counts taken at intervals) the striking deviation from normal in the nystagmus cases suggested the presence of a source of toxaemia.

Summary of Analyses of Cases

Tables of analyses of the cases are omitted owing to considerations of space, but the following is a brief summary of the findings on this point. Sixteen were found to be suffering from high blood pressure with renal damage. In many of these cases arterio-sclerosis was marked, and the urine contained albumin and granular casts. Three were suffering from toxic thyroiditis, one from lead poisoning contracted by drinking water from the hot-water system of his home, one from diabetes mellitus, one from post-encephalitic Parkinsonism, four from pyuria, and five from chronic purulent bronchitis. Thirty-four suffered from pyorrhoea alveolaris in a gross degree, and twelve had enlarged and septic tonsils. In every case there was ample evidence of toxaemia to account for the abnormal polynuclear picture.

DISCUSSION OF IMMUNITY

The highest recorded percentages of the incidence of nystagmus are Llewellyn's—namely, 35.2 per cent. in colliery officials, and Court's 34.75 per cent. in coal cutters. Taking Court's figures, because they apply to a definite occupation at the coal face, we are left to explain why the remaining 65.25 per cent. did not show nystagmus. Two reasons account for some of the deficiency. The first is that a certain number had not been employed at the coal face for a sufficiently long period to be affected; the second is that a certain proportion of the remainder did not suffer from an activating condition. There must, however, have been some of the 65 per cent. who had been working at the coal face for a sufficiently long period, and who had during that period passed through conditions—for example, infections—which could precipitate the onset of nystagmus. The probable explanation of their immunity is a personal refractoriness to the effects of toxins, just as of a given number of men who smoke strong cigars or who indulge in excessive amounts of alcohol, certain will develop tremors and other signs of toxaemia long before others. In some it will be days, in others weeks, in others months or years, with the same amount of alcohol or strong tobacco, before toxic signs become apparent.

TREATMENT

Until physicists invent some better means of illumination in coal mines, nystagmus will always be an occupational risk. Under present conditions its eradication involves administrative and executive schemes, the discussion of which is outside the scope of this paper.

We are not concerned with the question if the patient is "suffering from" nystagmus, in the legal sense; it is the certified case that most commonly comes under the direct notice of the medical attendant. The differentiation between cases "affected by" and "suffering from" nystagmus is difficult, and reliance must be placed to some extent on symptoms other than nystagmus itself. Such symptoms as vertigo, headache, and insomnia require careful consideration. They may not be due to the ophthalmic condition, but to concomitant cardio-vascular disease, chronic uraemia, etc.

Removal from the primary agent, the dim light of the mine, and removal or active treatment of any obvious source of infection are clearly the first steps. Errors of refraction should be corrected, but immediate benefit is not often apparent. In the acute case with violent eye movements the patient should have absolute rest in bed in a shaded room, and ought to avoid extreme variations in light. Reading or any occupation in which the eyes may be subjected to strain should be forbidden.

Nervousness and insomnia are often relieved by 10-grain to 20-grain doses of potassium bromide with drachm doses of ammoniated tincture of valerian, which may, however, require, in addition, some preparation of barbituric acid. Magnesium sulphate interrupts the path of stimuli in the neuro-muscular apparatus. In the few cases treated, 10 c.cm. of a 20 per cent. solution of the chemically pure salt given intramuscularly appeared to have a decided effect. As the whole of the salt is excreted in forty-eight hours, there is no cumulative result if the dose has to be repeated every other day. Toxic symptoms—narcosis and anaesthesia—are instantly relieved by an intramuscular injection of an active calcium preparation, but the risk of such signs developing with this dose is so small as to be negligible. The respite given to the myoneural apparatus by magnesium sulphate would appear to be sufficient to allow it to recover its normal functions.

The post-nystagmic neurasthenia which sometimes persists for months or years after the movements of the eyeballs have ceased may be treated by a strict Weir Mitchell regime and psychotherapy.

CORONARY THROMBOSIS AND MYOCARDIAL INFARCTION, WITH GLYCOSURIA

BY

NORMAN CRUICKSHANK, M.D., M.R.C.P., F.R.F.P.S.

VISITING PHYSICIAN, SOUTHERN GENERAL HOSPITAL, GLASGOW; ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY; SENIOR ASSISTANT TO THE MUIRHEAD PROFESSOR OF MEDICINE

Glycosuria associated with coronary thrombosis is now becoming recognized as a definite syndrome. The following case is of interest because it illustrates this syndrome, and because the course of the patient's illness presented some unusual features.

CLINICAL HISTORY

A retired railway porter, aged 68, came under my care in the Glasgow Royal Infirmary. He had a severe degree of cardiac failure; there was oedema of the limbs, back, and face, also cyanosis and orthopnoea. There was no anginoid pain, pericardial friction, or leucocytosis. The cardiac area was enlarged, the left border of dullness being one inch outside the nipple line and the right border at the right sternal margin. The heart sounds were of poor quality and the beats irregular in force, but there were no murmurs. The radial pulse was regular, the rate being 96. The radial and brachial arteries were thickened and tortuous, and the blood pressure was 140/104 mm. Hg. The urine contained a cloud of albumin, and there was incomplete reduction of Fehling's solution. On clinical examination no arrhythmia could be made out, but an electrocardiogram showed the abnormalities typical of branch-bundle block. QRS had a W-shaped deformity in all the leads, with distinct prolongation in Lead 1. There was also a tendency to inversion of T in Lead 1. The patient's condition did not improve. There were no attacks of precordial pain, but the signs of gross cardiac failure increased, and he died fifteen days after admission to the ward.

POST-MORTEM EXAMINATION

A post-mortem examination was made by Dr. Alice J. Marshall. The heart was soft and there was marked dilatation of the right auricle and right ventricle. There was an infarction of the muscle of the left ventricle involving the whole of the apical region and extending outwards for at least two inches on the anterior wall. In the left lateral wall of the left ventricle there was also a small recent infarction which lay midway between apex and base, in the line of the left lateral descending branch of the posterior coronary artery. Old thrombus was adherent to the inner surface of the left ventricle over the infarcted area. There were no gross changes in the valves, but the aorta showed advanced syphilitic aortitis. The orifices of the coronary arteries were of normal calibre, but the vessels were atheromatous. The right coronary artery was patent throughout its course, though its walls were much thickened. There was marked narrowing of the main descending branch of the left coronary artery, three-quarters of an inch from its orifice, while the lateral descending branch was completely obstructed by old thrombus about one inch from its orifice. The left lateral transverse branch was sclerotic. Other points worthy of note were the presence of advanced chronic interstitial nephritis, and fibrosis of the pancreas. There was hypostatic congestion of the lungs, chronic cholecystitis, and gastro-intestinal catarrh.

PREVIOUS HEALTH

The previous history of the patient contains some points of importance. He had been an apparently healthy man until about three years before his death, and had never suffered from any serious illness. When he was about 65 years of age he began to complain of cramp-like pains in the legs, which he regarded as rheumatic in nature. He then had a minor injury to one of his toes, and, as healing was slow, he was admitted to a surgical ward in the Royal Infirmary. It was then found that he had glycosuria, but this symptom cleared up without any intensive treatment.

About seven months later he began to have swelling of his feet, and dyspnoea on exertion. After being treated at home for six weeks, he was admitted to Professor Hunter's ward in the Royal Infirmary suffering with orthopnoea, cyanosis, and generalized oedema. The urine contained albumin and casts as well as 0·5 per cent. of sugar. The Wassermann reaction of the blood was positive. Examination of the heart at this time showed a degree of decompensation, but not much increase in the area of cardiac dullness. The sounds, particularly those at the apex, were of poor quality; the second sound at the base was accentuated. No murmurs were heard, and the rhythm was regular. The pulse rate was about 96, and the blood pressure was 140/90 mm. Hg.

Shortly after admission to the ward the patient's condition began to improve. The signs and symptoms of cardiac insufficiency became less severe, and the blood pressure rose to 170/120. He had been given large doses of digitalis, and after he had been under treatment for about a month a 2:1 heart-block developed, the pulse rate falling to 54. The block seems to have cleared up, for the pulse was running between 80 and 96 for several weeks before the patient was sent home. The glycosuria, which was associated with a hyperglycaemia (blood sugar = 180 mg. per 100 c.cm.), was rather resistant to treatment, but the urine eventually became sugar-free on a diet of 1,329 calories covered by 40 units of insulin. When the patient was discharged from the ward after eight weeks he appeared to be in fair health, and when he came up to report himself a month later he was still free from symptoms of cardiac failure and there was no glycosuria. His insulin had been cut down, and his diet was only slightly modified.

About five months after leaving hospital the patient developed dyspnoea, cough, and oedema. These symptoms continued to increase in severity up till the time of his second admission to the ward a month later.

COMMENT

The possibility of a relationship between coronary disease and diabetes was suggested in 1922 by Levine,[1] who found that in a series of cases of angina pectoris 7 per cent. of the patients had previously shown well-defined diabetes. The same writer in 1929,[2] in analysing a series of 145 cases of coronary thrombosis, found either glycosuria or a history of diabetes in 34 (23·7 per cent.). In some of these patients there was only a transient glycosuria during the early days of the attack; in others there were large quantities of sugar in the urine, and it was considered that a well-established diabetes was present. Between these extremes there were cases in which no appreciable amount of sugar appeared in the urine, even in the days immediately following a coronary occlusion, in spite of the fact that diabetes had been found previously and had been controlled by dietary measures. Levine considers that the relation of glycosuria to coronary thrombosis is a causal one, and states that "among the disease entities that are etiologically related to coronary thrombosis, diabetes is second in importance only to a previously existing hypertension." It seems more probable that the two conditions result from atheromatous changes in the coronary and pancreatic vessels respectively. It is difficult to imagine how glycosuria *per se* could determine the onset of coronary thrombosis.

In the case here recorded there are several points of special interest. The first is the widespread distribution and the severity of the atheroma, which affected not only the coronary circulation, but also that of the kidneys and the pancreas. The myocardium, the kidneys, and the pancreas all showed fibrosis and degenerative changes at necropsy, while clinically there occurred hypertension followed by cardiac failure, albuminuria, and glycosuria. Another point is the slow development of the extensive myocardial infarctions. These produced increasing cardiac failure, but never gave rise to the cardinal signs and symptoms which make up the clinical picture of coronary

hrombosis. It is remarkable, too, that a glycosuria so evere as to require 40 units of insulin per diem for its ontrol should have cleared up in spite of progressive leterioration in the state of the cardio-vascular system. This is all the more surprising when it is remembered hat during the patient's first residence in hospital the blood sugar had been well above the limits of normal, and that at post-mortem examination the pancreas was found to be shrunken and fibrosed. It seems possible that these variations in the carbohydrate metabolism may have been related to the chronic inflammation which was present in the biliary tract and to the pathological state of the kidneys.

SUMMARY

1. A case is described in which syphilitic aortitis, coronary thrombosis, and extensive myocardial infarctions were associated with glycosuria and hyperglycaemia.

2. Widespread atheroma with degenerative and fibrotic changes in the kidneys and pancreas and chronic inflammation in the biliary tract were found at necropsy in addition to the cardiac lesions.

3. The relationship between glycosuria and coronary thrombosis is discussed. It is considered more probable that these two conditions result from a common cause (vascular degeneration) than that glycosuria is an etiological factor in the production of coronary thrombosis.

I wish to thank Professor W. K. Hunter for permission to use the clinical records of this case, Dr. J. H. Wright who made the electrocardiogram, and Dr. Alice J. Marshall who performed the necropsy.

PLEURAL EFFUSION*

BY

L. S. T. BURRELL, M.D., F.R.C.P.

SENIOR PHYSICIAN, ROYAL FREE HOSPITAL; PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST

Pleural effusion occurs under several conditions, and its treatment is largely dependent on the cause and character of the fluid. For practical purposes effusions may be considered as either clear or thick, and I suggest the following classification.

A. CLEAR EFFUSION

Causation	Appearance	Coagulable Protein	Specific Gravity	Cytology
1. Transudates: Renal	Very pale	Per cent. 2	1008	Endothelial cells
Cardiac	Pale yellow	3	1016	
Neoplasm	Pale yellow or haemorrhagic	3	1016	
2. Exudates: Tuberculous	Straw colour	Over 4	1020	Small lymph.
Pyogenic	Turbid yellow	Over 5	1024	Polymorph.

B. THICK EFFUSION

1. Non-purulent opaque fluids vary from the cloudiness due to a slight excess of cells to the dense opacity of true chylous effusions. The density may be increased by the presence of blood. A true haemothorax is usually the result of trauma, but bleeding with an effusion is not uncommon, especially in malignant disease; it occurs in about 50 per cent. of cases of carcinoma of lung. Haemorrhage does occur in tuberculosis and other effusions, and should not therefore be taken as diagnostic of neoplasm. The fluid may be rendered opaque by the presence of cholesterol in an effusion of long standing, or by cells which have undergone fatty degeneration. True chylous effusions are not common, but may occur as a result of occlusion of the left subclavian vein, injury to the thoracic duct or pressure on it by tumours, or by filariasis.

2. Purulent effusion or empyema may be due to one of many causes, such as malignant disease, ruptured abscess of lung, septic emboli, actinomycosis, etc., but for practical purposes it may usually be considered as (*a*) pneumococcal, (*b*) streptococcal, or (*c*) tuberculous.

CLEAR EFFUSION

Before considering treatment I should like to say a little more about the laboratory findings of these fluids. On microscopical examination a few red corpuscles are usually seen. Their presence may be due to bleeding as a result of the pleural puncture, but they are not of clinical significance unless they are sufficiently numerous to be observed by the naked eye. Polymorphonuclear cells may also be present in proportion to the red corpuscles, but if these white cells are in excess it suggests that the fluid is due to a pyogenic organism, and that it will probably become purulent. Eosinophil cells may be regarded as intermediary between an acute infection where polymorphonuclear cells are in excess and a chronic state in which small lymphocytes predominate. A large number of eosinophil cells is said to be evidence against tuberculosis; it also suggests that the fluid will not become purulent. Eosinophilia is present in only 35 per cent. of cases of hydatid disease. As a rule, hydatid cysts of the lung do not leak; unless they do, eosinophilia does not occur. Hydatid fluid may be confused with pleural effusion; it is characterized by the presence of hooklets, not of eosinophil leucocytes. Usually it is like water, but during suppuration it resembles water into which one or two drops of milk have been put. Small lymphocytes occur in chronic inflammatory conditions, the commonest example of which is tuberculosis; therefore an excess of small lymphocytes strongly suggests this disease. Syphilis of the pleura is extremely uncommon, but when it does occur there is an excess of lymphocytes. Endothelial cells come from the lining of the pleura, and are in excess in transudates. They are rarely present in excess in cases of tuberculosis or of pyogenic infections, so that if renal or heart disease can be excluded, a preponderance of these cells in a pleural effusion makes us think of neoplasm. They have sometimes been mistaken for carcinoma cells, especially when they have undergone some degree of degeneration. Lymphocytes have been confused with sarcoma cells, but it is doubtful if neoplastic cells are ever present in an effusion; if they occur, it is very seldom, though they have often been described in error. The absence of tubercle bacilli should not be taken as evidence that the condition is non-tuberculous, for these organisms are hardly ever found in the early stages of an effusion unless a very large quantity of the fluid is used. The bacilli can usually be found in long-standing effusions, and they are present in almost every case of tuberculous empyema.

Treatment of Clear Effusions

When pleural effusion forms in a case of renal disease it is usually bilateral. Repeated aspiration is necessary, as the fluid tends to reaccumulate quickly. In cardiac cases it is best to remove the fluid early, as even a small collection in the pleural cavity embarrasses the heart. In the case of neoplasm, aspiration is necessary only when dyspnoea or pressure symptoms make the patient uncomfortable. I have seen a case of mediastinal tumour and a large effusion which, although the patient lived for six months, did not re-form after aspiration. As a rule, the fluid rapidly reaccumulates, especially in a case of endothelioma of the pleura. Indeed, the presence of an effusion which re-forms after each aspiration is very

* A paper read to the Portsmouth Division of the British Medical Association.

suggestive of endothelioma. In one case I withdrew a quantity of fluid three times in one day.

Most of the cases are tuberculous, and I think every case of pleural effusion should be regarded as of tuberculous origin unless some other definite cause for it can be found. It is necessary to take a few cubic centimetres of the fluid for analysis as soon as a diagnosis is made, but, apart from this, I think aspiration should not be performed except for one of three reasons:

1. To relieve urgent pressure symptoms, or to treat a case in which the fluid is not absorbing naturally.
2. To convert an effusion into a pneumothorax if the underlying lung has active disease.
3. To allow the lung to re-expand if there is active disease spreading in the other lung.

With regard to the first indication, it is not often necessary to aspirate, as almost always the fluid becomes absorbed in time. There is usually a rise of temperature at the beginning; this may continue for several weeks, suggesting an empyema, but in time the temperature will fall without aspiration, unless there is active disease in the lung. If the temperature persists and the patient is ill after six weeks, some of the fluid should be aspirated, but if more than 10 ounces are removed it is best to replace the fluid with air or oxygen. Air should be used if it is intended to make a permanent pneumothorax, but oxygen, which is more quickly absorbed than air, is indicated if one wishes the lung to re-expand. If, in spite of removing some of the fluid, the temperature does not settle, the remaining fluid should be completely aspirated and replaced with air or oxygen. In this case, however, it is almost certain that there is active disease in the underlying lung, and as the lung re-expands it should be carefully examined for any sign of disease, and repeated *x*-ray examinations should be made. One must remember that tuberculosis starts in the lung and spreads into the pleura; it does not start in the pleura and spread back into the lung; consequently when one sees a case of pleural effusion one should assume that there is disease in the lung, although in most cases it is not active, and does not develop into clinical disease. Some 40 per cent. of cases, however, do go on to clinical tuberculosis, and for this reason it is necessary to keep a patient under careful supervision and give him thorough after-treatment following pleural effusion.

In treatment by pneumothorax pleural effusion frequently forms, and in my opinion this is a true tuberculous exudate, and is not due to irritation of the pleura, or to any mechanical cause. It has been stated that if the gas is heated, pleural effusion is not so likely to occur, but I have tried heating the gas, and have found an effusion developing to the same degree as in my other cases. I have also noticed no difference between the influence of summer and winter on the accumulation of fluid.

When the fluid is examined the only organisms found are tubercle bacilli, and in the great majority of cases these can be demonstrated after the first two months. Moreover, the cytology of the fluid suggests an exudate, and I have not known an effusion form in any case I have treated with pneumothorax for diseases other than tuberculosis, except in one case of an acute abscess, when there was a small amount of fluid for a short time. Pleurisy is such a common complication of pulmonary tuberculosis that one would expect an effusion to form if the parietal and visceral pleura were separated so that they could not become stuck together. An effusion forms in practically every case of spontaneous pneumothorax due to tuberculosis, but in those cases where air is quickly absorbed and there is no effusion the patient makes a complete recovery, and subsequently no evidence of tuberculosis can be found.

When an effusion occurs during treatment by artificial pneumothorax it keeps the lung collapsed so that the intervals between the refills can be increased by weeks, or even months. The fluid may remain clear and unabsorbed, but there are two dangers; one is that it becomes tuberculous pus, and the other is that, as it is absorbed, organization takes place, and the pneumothorax cavity becomes gradually obliterated. On thoracoscopic examination, white strands of fibrin may be seen in the fluid. Many cases of pneumothorax which terminate by obliteration in this way do very well, a satisfactory fibrosis occurs in the diseased part of the lung, and the healthy part begins to function again. If, however, it is desired to maintain the pneumothorax, the fluid should be aspirated from time to time, and if any signs of obliteration are found, the fluid should be completely removed and replaced by a 5 per cent. solution of gomenol in olive oil. Usually, after one or two aspirations, the fluid does not reappear.

TUBERCULOUS PURULENT EFFUSION

If an effusion changes into tuberculous pus the condition is much more serious. I have had a few cases in which the pneumothorax has been maintained and the patient has done well, in spite of having had a tuberculous empyema; but these are very exceptional, and the majority die. For this reason, as soon as a tuberculous empyema forms, I encourage the lung to re-expand by frequent wash-outs with Dakin's solution, leaving a negative intrapleural pressure. In most cases this is successful, the lung can be made to re-expand, and in favourable cases becomes a chronic fibroid lung. If, however, it does not re-expand, I advise thoracoplasty, provided there are no serious contraindications to the operation. The principles of treatment in a case of tuberculous empyema are therefore:

1. Remove the pus by aspiration, and not by open drainage. Wash out the pleural cavity with Dakin's solution in order to remove the fibrinous lining round the pleura and to encourage the lung to re-expand. If there is a bronchial fistula or perforation into the lung, as in a case of spontaneous pneumothorax, Dakin's solution is too irritating to use, and the pleura should be washed out gently with saline or methylene blue. When there is a large perforation, however, it is unusual for the lung to re-expand, and thoracoplasty becomes necessary.
2. If the lung fails to re-expand and to obliterate the pneumothorax or empyema cavity in spite of this treatment some thoracoplastic operation should be performed to obliterate the cavity.
3. Attend to the general condition of the patient.

PYOGENIC PURULENT EFFUSION

The treatment of non-tuberculous empyema depends almost entirely on whether the pus is free in the pleural cavity or whether it is pocketed. If it is free, the condition is, in effect, pyothorax, and any operation for drainage will convert it into an open pyopneumothorax, a condition in which the mortality is very high indeed. If there are no adhesions and the mediastinum is free, a wound which opens the pleural cavity on one side affects the pressure not only on that side, but to practically the same degree on the other. The result of this is that, during inspiration, some of the air that should enter the lungs through the trachea enters the pleural cavity through the open wound. If, therefore, the opening into the pleura is larger than that into the lungs through the larynx, it follows that the lungs will not expand, and the patient will die of asphyxia. This was found to be the case in gunshot wounds during the war, and also by experiments on dogs. In the case of pneumonia the lungs are already getting insufficient air, so that the effect of an open pneumothorax is still more disastrous.

The first principle of treatment, therefore, should be to avoid an open pneumothorax. This may be done by using a drainage tube with a valve, which allows the pus to leave but prevents air from entering the pleural cavity. It is usually better, however, to aspirate the fluid at first until adhesions have formed, when incision and open drainage can be performed if necessary, although a certain proportion of cases get well with aspiration alone. In practice it is found that pneumococcal empyema in lobar pneumonia occurs after the illness. The pus is thick, and there are adhesions, so that it is safe to resect a rib and drain the cavity. Moreover, by the time the empyema forms, the patient has, as a rule, recovered from the toxaemia of the pneumonia. For these reasons treatment by incision and drainage is usually successful in pneumococcal cases, and when once the pus is found to be thick, it is better to drain the empyema.

In streptococcal cases, however, the effusion forms early, whilst the patient is still suffering from the toxaemia of the disease. The fluid is at first cloudy and thin, and there are no adhesions, consequently incision and drainage is likely to be fraught with danger. Dr. W. J. Stone published the results of three series of cases.[1] In the first series 85 cases were treated by early operation and drainage, and the mortality was 61.2 per cent. In the second series 96 cases were treated by early aspiration and late operation, and the mortality was 15.6 per cent. In the third series 94 were treated by early and late operation, and had a mortality of 9.5 per cent. In some cases aspiration alone is sufficient, but in the majority subsequent drainage becomes necessary, and when once the fluid has turned into frank pus it is usually safe to operate. After operation, in every case of empyema, it is essential to wash out the pleural cavity frequently with Dakin's or some similar solution in order to encourage re-expansion of the lung, and to disinfect the pleural cavity. The principles, therefore, in the treatment of pyogenic empyema are:

1. Remove the pus, but always avoid an open pneumothorax.
2. Encourage the lung to re-expand and obliterate the empyema cavity. This should be done by washing out the cavity, and any drainage should be arranged so that air cannot enter from outside.
3. Sterilize the cavity by frequent irrigations.
4. Attend to the general condition and nourishment of the patient.

BATH TREATMENT FOR DEAFNESS

BY

JAMES ADAM, M.A., M.D.

SURGEON FOR DISEASES OF EAR, NOSE, AND THROAT, GLASGOW CITY HOSPITALS

Any measure which will help, even in a minority of cases, what is commonly called chronic progressive deafness is worth consideration, especially if it sometimes succeeds where the usually approved methods fail, and if it is a simple procedure capable of supervision by the general practitioner. The following case illustrates the point.

CASE I

A man, aged 42, consulted me in December, 1927, about deafness in the left ear, which had increased during the previous two years. There was no obvious retraction or thickening of the tympanic membranes, but he had difficulty in self-inflation. With the right ear he could hear a whisper across the room (say 15 feet away); with the left ear, 5 feet away. After treatment by catheter, bougie, and inflation for a year, the condition was worse. A whisper was then heard by the right ear at a distance of 5 feet; by the left ear, 2 feet. He was ordered hot baths, with a pound of commercial Epsom salts added to each bath; immersion for ten to fifteen minutes was advised at bedtime every second night for a week, once during the following week, and then once a fortnight. Within a week, the hearing distances for whisper were 15 and 9 feet (instead of 5 and 2 feet) for right and left ears respectively. By May, 1930, the distance for each ear had increased to 30 feet. Improvement is still maintained, and is valuable not only to himself but to his colleagues. The baths are still necessary, but they are taken at longer intervals.

As often happens with new treatment, this first case has perhaps been the most striking. The success induced me to try the method in other cases, and sometimes gratifying results were obtained.

CASE II

For many years the manager of a large business, aged 64, had increasing deafness for which I tried in vain the usual measures. Some years elapsed, during which he did not consult me, but after the experience mentioned I asked him to see me. On examination, the right membrane was dull and indrawn, the left was ruptured and atrophied, and the ossicles were bound in cicatrix. Conversation voice was heard 4 feet away on the right side, 4 inches away on the left side. The latter figure is naturally open to question, because of possible hearing by the right ear even when closed. After treatment by baths for two months, the distances were 10 feet and 2 feet respectively, to his great delight.

CASE III

A hospital matron, aged 33, had tinnitus in the left ear, and slight deafness. The Eustachian tubes were narrow; systolic blood pressure 100 mm. Hg. Resection of nasal septum, removal of tonsils, and passage of Eustachian catheter and bougie were all tried, with no obvious benefit. When the patient reached the age of 38, the tinnitus was worse and was in both ears. When, two years later, in May, 1930, a whisper was heard by both ears at 8 feet, I asked her to try baths. A fortnight later the figures were 21 and 25 feet respectively, tinnitus not having improved.

CASE IV

A lady, aged 60, complaining of deafness beginning in the left ear ten years earlier, came to see me in October, 1930. Both membranes were dull, and inflation by catheter was difficult and imperfect. She heard the conversational voice 15 inches away on the right side, and 5 inches away on the left; Weber referred to left. As there was no improvement on inflation, she was asked to try baths. At the middle of December, conversation was heard on the right side at 16 feet distance (instead of 15 inches), on the left at 10 inches.

CASE V

A man, aged 58, had noticed deafness and tinnitus in the right ear for five months. Both membranes were indrawn. A whisper on the right side was heard 2 inches away, but after three weeks of bath treatment the distance had increased to 7 feet; tinnitus was still present, but less marked.

The less chronic cases respond more readily. Those described above were probably "catarrhal" cases, with narrowing of the Eustachian tube—the type in which sweating might be expected to help. Encouraged, however, by the improvement in the cicatricial ear of the patient (Case II) mentioned above, I resolved to try baths in the following case:

CASE VI

A man of 39, who complained of deafness in the right ear after an explosion in the trenches in 1916, came to me in June, 1930; there was also tinnitus in the right ear. The left ear was normal; the right drum was "gone," ossicles adherent, no discharge. He was asked to try baths. The hearing for whisper before treatment was at a distance of 3 feet; after two months' treatment, at 60 feet.

One might expect benefit from this treatment in patients suffering from Ménière's complex, if it is tried early. I have had the opportunity in only two such cases, both late ones. In the first there was complete failure; in the second there seems to have been some success, as shown by the history.

CASE VII

A widow, multipara, aged 47, weight 12 st. 10 lb., height 5 ft. 3 in. was first seen in January, 1930. She had a typical Ménière's syndrome for three years, beginning in the left ear, in which she was now stone deaf. The right ear had been affected for two years. She had well-marked tinnitus and frequent attacks of giddiness on turning quickly; on going upstairs, she had to cling to the rail and sometimes fell. Tinnitus, giddiness, and deafness were worse at menstruation. She could just hear a loud noise with the right ear at 3 inches distance. The Wassermann reaction was negative. Baths did no good. They did not make her sweat till she added 2 lb. of magnesium sulphate to the bath. With this treatment, however, she persevered. She now hears loud speech at 5 feet, has no giddiness, and can walk up and down stairs with ease. The baths may have nothing to do with this improvement. The course of Ménière's complex is sometimes capricious, but anyone who has read Dederding's monograph[1] would consider treatment by sweating not unlikely to help; to be a real help it would need to be used regularly and before irretrievable damage is done to the inner ear.

This treatment is as yet in the tentative stage, but these notes may suggest to others that the method is worthy of trial. It is likely to succeed only in a minority of chronic cases, though it has had good results in cases in which the usual methods had proved an utter failure and in which treatment had been abandoned. Success is more probable in the less chronic cases and in acute cases. It fails when it fails to sweat the patient. Whether magnesium sulphate is essential I do not know; it is hygroscopic and has been used in packs for chronic rheumatism. Doubling the quantity of salt to the bath seemed effectual in causing the last-mentioned patient to sweat. Treatment by the emunctories is an old-established method, but far too little attention has been paid to the skin and to the effect of sweating on the mucous membranes; probably civilized peoples sweat themselves too little and pay a price in catarrhal affections. Thirty years ago treatment by pilocarpine was tried, but had only a short vogue as "the remedy was worse than the disease." Caution must be used with baths, too. Hot baths are exhausting and too risky for elderly, weakly, and cardiac patients; ten minutes immersion may be long enough, and should be followed by a brisk towelling and a warm bed.

CHYLOUS ASCITES COMPLICATING ABDOMINAL LYMPHADENOMA

BY

THOS. A. PRATT, M.D.
ASSISTANT PHYSICIANS, CITY OF GLASGOW FEVER HOSPITAL, KNIGHTSWOOD

AND

H. W. O. FREW, M.D., D.P.H

The presence of serous fluid in the peritoneal cavity may be due to a variety of causes, but it is very seldom that cases are reported in which the fluid is chylous in nature. One such case came under our observation, and was considered, on account of its rarity, worthy of record.

Case History

The history of the case dates from September, 1928, when the patient, who was a young man of 20 years, first complained of weakness, tiredness, and loss of flesh. Though able for a time to carry on his work, he had ultimately to give it up on account of the weakness. In January of the following year he developed an attack of influenza, and during convalescence from this illness noticed for the first time, owing to slight pain a fullness of his abdomen. It was not, however, till coughing and spitting became troublesome that he consulted his doctor. From the history given, the presence of tuberculosis was suspected, but examination of the chest revealed only a few moist sounds at the base of both lungs. *X*-ray examination confirmed the absence of any evidence of tuberculosis of the lungs. The sputum was examined, and was found to be negative for tubercle bacilli. From this time till his admission to hospital his condition rapidly became worse. The general weakness increased, the abdomen became much more distended, and he was in consequence confined to bed.

When admitted to hospital, in the middle of May, the patient's condition was obviously serious. He appeared thin, wasted, and cyanosed, and complained of pain in his left thigh and leg. The distension of the abdomen was marked, and gave rise to considerable respiratory embarrassment. In the feet and legs there was a moderate amount of oedema. Examination of the chest was negative, save for signs of congestion at both bases, and the sputum was negative for tubercle bacilli. The heart showed no evidence of organic disease. The urine, which was diminished in amount, contained albumin. During the succeeding days the oedema present in the legs spread upwards till even the chest wall was involved, and with the increase in the abdominal swelling the breathing became more distressed.

On May 24th, 1929, paracentesis was performed, and 26 ounces of milky fluid were removed from the abdomen. The procedure afforded relief, which, of course, was only temporary, and the operation had again to be performed. Altogether the abdomen was aspirated six times, and 38 pints of fluid were withdrawn. When the abdomen was palpated just after paracentesis a hard fixed mass was felt in the epigastric region. In addition to the large mass, smaller masses were felt throughout the abdomen. In spite of these aspirations his condition gradually became worse, and he died on June 18th, 1929.

The fluid which was removed from the abdomen was subjected to chemical and bacteriological examination. To the naked eye it had the appearance of milk. Under the microscope it appeared as a fine fat emulsion, in which were observed a few red corpuscles and a few leucocytes containing fat globules. A differential cell count was performed, and the mononuclear leucocytes were found to be slightly in excess of the polymorphonuclear leucocytes. Stained smears failed to reveal acid-fast bacilli, and no growth resulted from inoculation of culture media. A guinea-pig was inoculated with the chylous fluid, and when killed at a later date was found to be normal.

The result of the chemical analysis was as follows:

Fat	11.42 per cent.
Proteins	11.57 "
Other organic matters	1.10 "
Mineral salts	7.89 "
Total solids	31.98 "

Of the mineral salts 58.22 per cent. consisted of sodium chloride.

Necropsy

The body appeared very emaciated. Post-mortem mottling was most marked over the right side of the chest. The abdomen was greatly distended, the linea albicantes being very marked, especially on the right side. When the body cavities were opened they were found to contain large quantities of milky fluid; 140 ounces were recovered from the abdominal cavity, 50 ounces from the left pleural cavity, and 36 ounces from the right pleural cavity. The fluid from the abdomen seemed to be of a more yellowish colour than that collected from the pleural cavities.

Heart.—The pericardium was found to contain about 6 c.cm. of straw-coloured fluid. The heart was small and in a state of contraction. The surface of the organ presented a whitish appearance, and the blood vessels were outlined by a white marginal line on each side. The heart muscle in its cut surface presented a finely streaked appearance due to the presence of delicate white lines radiating unevenly towards the surface. The muscle itself did not assume the normal reddish appearance, being dull and glistening and slightly brownish in colour.

Lungs.—Beyond a slight degree of hyperaemia the lungs appeared to be normal. The left lung was slightly adherent at its base, but no evidence of involvement of the bronchial glands was discovered.

Diaphragm.—The pleural surface of the diaphragm was found to be studded with nodules varying from 1/4 inch to 1½ inches in diameter.

Spleen.—The spleen was greatly enlarged and firmly adherent to the diaphragm and other neighbouring structures, and was removed with great difficulty. On section, a very large portion was found to consist of a tumour which was growing at the periphery and in offshoots into the remaining splenic tissue. In the greater part of its extent the tumour appeared to be undergoing a process of necrosis with softening and cavity formation at the centre. When it was sectioned a thick yellowish fluid escaped from the cavity.

Liver.—The liver was firmly adherent to the diaphragm and to a large mass of tissue which occupied the epigastrium. The capsule of the organ was marked by white lines, which had a root-like appearance. A large rounded tumour, measuring 3 by 2 inches, occupied the lower surface of the right lobe. It was subcapsular and compressed the liver tissue. At only one place, however, had actual invasion of the liver occurred. When sectioned the liver had a dull, greyish colour, and at one point of the right lobe approached the nutmeg appearance.

Kidneys.—The right kidney was shelled out from its capsule, which was firmly adherent to dense surrounding tissue. It presented in a marked degree the foetal lobulation. Apart from slight hyperaemia it appeared to be otherwise normal. The left kidney was also surrounded by dense adhesions, but its capsule stripped easily, revealing the fact that the organ was also misshapen. It was sectioned, and this alteration in shape was found to have resulted from the presence of two cysts, one projecting into the other. In other respects the renal tissue appeared normal. Both suprarenals were enveloped by fibrous tissue, but otherwise appeared normal.

Intestines.—The small intestine had a greyish appearance, and its wall was thickened and oedematous. The duodenum was found to emerge from a large tumour mass which occupied the epigastrium. The large intestine was also greyish and thickened in appearance. The wall of the colon and its mesentery were finely mottled white from engorgement of the lacteals. The transverse colon was firmly adherent to the tumour mass in the epigastrium, and its mesentery was studded with small tumour nodules. When the intestine was opened the margin of the ileo-caecal valve was ulcerated, and at a short distance from it there was an ulcer, 5/8 by 1/4 inch, with dark hyperaemic margin and yellowish floor. The valvulae conniventes were whitened and fringe-like from engorgement of the lacteals. This engorgement was not so evident to the naked eye, but with transmitted light the lacteal vessels appeared markedly engorged.

Stomach.—The stomach overlay the tumour mass, and was firmly bound down to it. On removing the stomach by blunt dissection the mucous membrane was intact, save for a small commencing ulcer on the posterior wall. Judging from the mucous surfaces there was no invasion of the stomach wall by tumour tissue, but the section showed that the wall in its outer part was invaded by the tumour growth.

Mesentery.—The surface of the mesentery had a slate-grey appearance, and the lacteals were all very conspicuous. The mesenteric glands were much enlarged, and had a finely-mottled yellowish-white appearance.

When the abdominal viscera were removed a large mass was exposed, almost filling the epigastrium. It was firmly adherent to the prevertebral fascia and to the diaphragm, and it extended down into the lumbar region. On closer examination it was found to be composed of smaller masses firmly adherent to one another. When sectioned the cut surface appeared white and glistening. Portions of the tumour mass were subjected to histological examination, and the following features were observed. There was a marked proliferation of the endothelial cells, which had single and occasionally multilobed nuclei. Larger cells of a pseudo-giant-cell type were present. Polymorph leucocytes and eosinophil cells were definitely increased. Sections of the stomach wall demonstrated that the inner portions, mucosa, submucosa, and most of the inner muscular coat were not involved. The greater part of the muscular wall, extending to the serous surface, displayed marked lymphocytic infiltration. Endothelial cells were observed in places. From these findings a diagnosis of lymphadenoma can be made.

Discussion

In most of the recorded cases of lymphadenoma, more especially of the abdominal type, the diagnosis has been difficult, the condition being mistaken for tuberculosis, syphilis, sarcoma, and other tumours. In the present case the initial diagnosis was one of tuberculosis, and, although repeated examinations failed to confirm this opinion, it was only after histological examination of a section of the tumour tissue obtained at the post-mortem examination that the final diagnosis of lymphadenoma could be made. It is of interest, too, that while the superficial glands were not appreciably affected, the spleen showed gross involvement. This latter fact has led certain observers to recognize what they term the splenic type of abdominal lymphadenoma.

Other noteworthy points were the absence of involvement of the alimentary tract apart from the slight infiltration of the stomach wall, the relatively slight involvement of the liver, and the freedom of the kidneys from any evidence of new growth.

The analysis of the chylous fluid also revealed certain interesting features when compared with the results of similar analyses of chylous ascites obtained from cases of abdominal tuberculosis or cancer (see Table).

	Present Case (Lymphadenoma)	Tuberculosis. Boy aged 13 years	Cancerous Growths
	Per cent.	Per cent.	Per cent.
Fat	11.42	10.30	9.48
Proteins	11.57	23.78	21.68
Other organic matters	1.10	8.02	11.585
Mineral salts	7.89*	9.95	1.595
Total solids	31.93	59.15	43.795
			Loss 0.510

*58.22 per cent. of the mineral salts consisted of sodium chloride.

As will be seen from the above table, the percentage of protein present in this case of lymphadenoma was roughly only half the amount noted in the other conditions. Protein and fat were present in approximately the same proportions, while in the other two diseases the amount of protein was much in excess of the fat. These findings raise the question of the possible diagnosis of the condition by the examination of the chylous fluid obtained from the abdomen.

We desire to express our thanks to Dr. R. M. Buchanan and Dr. W. R. Wiseman, and to Mr. F. W. Harris, F.I.C., for their assistance in the examination of specimens.

SURFACE TENSION OF SERUM IN GENERAL PARALYSIS

AN AID TO DIAGNOSIS

BY

B. H. SHAW, M.D.

MEDICAL SUPERINTENDENT, COUNTY MENTAL HOSPITAL, STAFFORD

During an investigation of the surface tension of syphilitic serum an interesting fact was observed, which appears to throw some further light on the nature of amboceptor and tends to confirm Friedemann's view that it is a globulin soap compound. The finding may also serve as a help in diagnosis, since nothing could be simpler than the technique of its application.

By adaptation of the torsion balance capable of weighing from 1 to 500 mg., a method was devised of estimating surface tension of fluids in a direct and accurate manner—namely, by suspending a small platinum ring (about 1 cm. in diameter 0.0076 wire) by a light thread from the balance, and allowing it to float on the surface of the fluid. In carrying out the test 0.25 c.cm. of serum is

added to 50 c.cm. of distilled water in a small beaker; the fluid is drawn back into the pipette and forcibly expelled again a few times, thorough mixture being ensured. The beaker is suitably adjusted under the limb of the balance. The suspended ring is then lowered on to the surface of the fluid, the lever of the instrument evenly moved, and the reading in milligrams just necessary to make the ring part company with the fluid, less the weight of the platinum attachment, gives an accurate measure of the surface tension.

As might be expected there is considerable variation in the surface tension of serum diluted 1 in 200 in this manner, but in all persons examined so far there is a consistent variation from normal in the serum of those with general paralysis when it is inactivated at 56° C. for thirty minutes. In conditions other than general paralysis this inactivation has the effect of raising the surface tension; at any rate no definite degree of lowering is observed, while as regards the serum of general paralytics the reverse is the case.

The following tables, giving the pull-off readings of surface tension in milligrams, illustrate this difference.

General Paralysis, Wassermann Reaction Positive

	Tension in mg.		Loss on Inactivation in mg.
	Fresh Serum	Inactivated Serum	
A.	314	214	100
M.	344	311	33
C. H.	335	305	30
E. T. B.	340	310	30
T. B.	325	300	25
D. J.	330	310	20
W. H. P.	330	365	25
G. B.	330	365	25
J. W.	358	340	18
J. Br.	363	345	18

Non-syphilitics, Wassermann Reaction Negative

	Tension in mg.		Gain on Inactivation in mg.
	Fresh Serum	Inactivated Serum	
B.	294	329	35
M.	330	305	5
B.	310	310	0
F.	295	317	22
H. E.	345	345	0
D. M. N.	345	350	5
T. G.	335	365	30
S. A.	350	350	0
A. S.	345	355	10
W. N.	342	343	1
T. H. C.	370	385	15
W. S.	387	404	17

In cases of syphilis investigated up to the present showing no clinical signs of general paralysis this alteration in tension has not been observed, and consequently it may be of value as an aid to diagnosis in incipient syphilitic meningo-encephalitis, and has no doubt some relation to the stuff positives present in this condition. In high dilutions of serum in distilled water precipitation soon occurs, consequently the reading should be quickly taken after thorough mixture.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

CUTANEOUS HORN ON AN AMPUTATION STUMP

The case reported below appears to be unique. Turner[1] in 1815 described a cutaneous horn arising in a scar, but on careful search of the literature since that date no

reference to the condition in relation to an amputation was found. Rhodenburg[2] stated that in 13 per cent. of cases epithelioma developed at the base of the horn, but despite the long history this had not occurred in our case.

The patient, an Arab woman aged 70 years, had a cutaneous horn arising from the end scar of an amputation of the foot. This had been present for many years without special inconvenience, but recently the slightest touch on it caused her intense pain, which radiated up the leg. The amputation had been carried out in the days of the Mahdi, some fifty years previously, for Madura foot, by a native operator.

On examination there was found to be a slow septic process at the base of the horn, but no evidence of epithelioma, nor were the inguinal glands enlarged. The "ram's horn" appearance of the growth is well shown in the photograph. Reamputation was performed (by F. E. M.). A large neurofibroma was found in the base of the scar, and the nerve leading to it was followed up into the leg, crushed, and divided. The patient was discharged cured.

We are indebted to Mr. O. F. H. Atkey, C.M.G., Director Sudan Medical Service, for permission to publish this note.

British Medical Association

CLINICAL AND SCIENTIFIC PROCEEDINGS

CHESTERFIELD DIVISION

A crowded meeting of the Chesterfield Division was held on March 13th, when Dr. A. NIVEN ROBERTSON, chairman of the Division, presided. Dr. ROBERT HUTCHISON gave a British Medical Association Lecture on rheumatism in childhood.

Rheumatism in Childhood

Dr. Hutchison began by saying that the importance of rheumatism in childhood was chiefly due to its serious consequences and not so much to the acute infective outbreak itself. Mentioning the fact that the disease was definitely of microbic origin, he went on to outline its distribution, dealing with this under three headings: (*a*) geographical; (*b*) social; (*c*) age. Rheumatism in children was chiefly localized in the temperate zone, with variations in every country; thus it was common in Edinburgh and London, but rarer in some parts of the British Isles. These variations, Dr. Hutchison thought, might be due to the extent of moisture in the affected

areas. The upper classes were almost immune, but the better class of artisan and the lower middle class were particularly prone. Acute rheumatism was never found in children below the age of 2½ years.

Dealing with the "soil" and the "seed," Dr. Hutchison said that the kind of child usually affected was the healthy-looking child with dark hair, clear skin, bluish-white sclerotic, and particularly well-formed incisor teeth, sometimes known as "grave-stone" teeth. The red-haired child was also prone to rheumatism, often of malignant type. Dr. Hutchison mentioned the difficulty in the definite recognition of the infective organism. The latest view was that a streptococcus allied to the scarlatina organism was responsible, but there might be many types of streptococci involved. In all probability entry was made through the throat, but the speaker was careful to exculpate the tonsils, and did not advise their removal solely for prophylactic treatment. Most probably an acute pharyngitis preceded an attack of acute rheumatism by ten to twenty-one days. Damp and cold weather favoured the development and recrudescence of acute rheumatism. The infective organism invaded chiefly the tendinous portions of the muscles, the joints, skin, and the blood, which often showed an anaemia, owing to the rapid fall in the red blood cell count (often as much as a million in a day).

The trivial pains commonly known as "growing pains" were often the earliest indication of the condition, being felt behind the knees or round the ankles. Arthritis was soon noticeable because of the swelling of the joints in more than one situation. An erythema of the skin was another manifestation, showing large crescentic areas over the trunk and limbs. Nodules were found in the skin where bones approached near the surface—for example, at the elbow, knee, and occiput. The larger the nodules, the more severe the attack. Though nodules of themselves were not important they accompanied inflammatory changes in the heart.

Rheumatic carditis was of great importance; the heart tissues could be involved separately or simultaneously. Endocarditis was the earliest sign, and produced a short, local, and superficial systolic murmur heard at the apex; this was followed by a reduplication of the second sound at the apex, then a mitral diastolic murmur, and, last of all, a mitral presystolic murmur indicative of mitral stenosis. Myocarditis was more difficult to detect and was more important than endocarditis. The two chief signs were dilatation of the heart and alteration in rate. The pulse rate must be studied in all cases, and was of far more value than the temperature chart. Pericarditis was diagnosed by a superficial friction over the precordium. There was rarely a large fluid effusion. "Bamberger's sign" was very important. Under differential diagnosis, Dr. Hutchison mentioned that acute rheumatoid arthritis, acute staphylococcal infections, acute osteomyelitis, acute poliomyelitis, and infantile scurvy must all be eliminated.

Discussing treatment the lecturer said that acute rheumatism was not preventable, but much could be done in the protection of susceptible children by taking great care of them. He did not recommend the massive use of salicylates. Prolonged rest was necessary in all heart lesions; opium was of use in pericarditis and restlessness. In pericarditis, leeches, blisters, and ice bags could be applied. The convalescence should be well watched to prevent relapses.

Dr. A. E. NAISH (Sheffield), in proposing a vote of thanks to Dr. Hutchison, commented on the masterly way in which the lecture had been given. The vote was seconded by Dr. H. W. POOLER (Chesterfield), and was warmly accorded.

Reports of Societies

EXCRETION UROGRAPHY

At a meeting of the Section of Urology of the Royal Society of Medicine, held on March 26th, with Mr. S. G. MACDONALD in the chair, Professor A. VON LICHTENBERG of Berlin spoke on the principles of excretion urography and new advances in its technique.

Professor v. Lichtenberg said that he had based his conclusions on the study of over 2,000 cases and of seven intravenous contrast substances. Five of the latter were now being reported on for the first time, and of these D.40, or uroselectan B, had decided advantages. The older method of instrumental urography had been able to demonstrate anatomical defects only, but excretion urography was capable of showing certain physiological details. For example, the degree of elimination of the contrast substance was an index of kidney function. Moreover, the excretion method made it possible to visualize dynamic disturbances; instrumental urography could never produce an accurate picture of the pelvis of the kidney, because it was always either distended with fluid or contracted owing to irritation. By the excretory method it was possible to observe the peristalsis of the pelvis; not only the anatomical changes, but also the physiological details of the disease were shown. The urinary tract could be studied as a physiological entity, and the excretory method emphasized system pathology rather than organ pathology.

The most important quality in a contrast substance was that it should be well tolerated on intravenous injection. Secondly, the quantity eliminated must be sufficient to give satisfactory visualization. The absolute quantity of the substance eliminated was no criterion of its suitability for excretion urography; its usefulness depended neither on the proportion eliminated through the kidney nor on the concentration in the blood. The only requirement was that the quantity eliminated should appear in the urine as quickly and in as strong a concentration as possible. The accompanying diuresis was important because it influenced the concentration of the contrast substance in the urine.

The five new substances—D. 34, D. 50, B. 1015, D. 40, and Sch. 122—compared favourably with abrodil and uroselectan, which were already on the market. In the first place the dosage with the new substances was considerably lower; when using them only one-fifth to three-fifths of the amount of iodine previously believed to be necessary was injected. It was possible to obtain better visualization with 2½ grains of D. 34 than with 12 grains of uroselectan. This seemed to destroy the postulate that much iodine was necessary for the success of excretion urography, and emphasized the importance of physiological rather than chemico-physiological factors. Secondly, the new substances were eliminated more rapidly and in greater concentration than the old substances. With abrodil and uroselectan the highest concentration occurred three-quarters to one and a quarter hours after injection; with the new substances, however, the highest concentration was reached within half an hour, and with D. 40, which gave the highest concentration of all, the maximum was attained a quarter of an hour after injection. Good solubility and high iodine content were only relatively important; the absolute value of the various substances rested on a group of factors, some of which were still unknown. Apart from toxicity, elimination appeared to be the most important factor. It was not the amount of any substance introduced, but the amount eliminated, which gave the optimum success, particularly when the

eliminated substance illustrated the concentration power of the kidneys.

In some cases where excretion urography was used to supplement instrumental urography, the detail of the pelvis and calyces, as shown by the excretory method, was finer. In other cases, where the kidney function was gravely impaired, the excretory method gave little or no shadow, denoting a severe degree of injury, and thus indicating the damage to the concentration power of the kidney; instrumental pyelography was, of course, also valuable in such cases. When mechanical interference prevented the introduction of a ureteric catheter, and when at the same time the kidney function was seriously impaired, both methods failed. In a large series of cases in which instrumental pyelography failed to give information, excretion urography furnished exceptionally good visualization. These cases fell into three groups: first, cases in which instrumental pyelography failed and excretion urography gave good pictures; secondly, cases in which instrumental pyelography furnished defective, and excretion urography good, pictures; and thirdly, cases in which the failure of certain portions of the pelvis to fill with instrumental pyelography caused diagnostic difficulties which were clarified by excretion urography.

Dr. P. B. HUGHES exhibited Professor v. Lichtenberg's remarkable collection of slides demonstrating the value of the new contrast substances, D. 40 in particular. These included illustrations of cases in which obstruction by stone had prevented the performance of instrumental pyelography, and in which excretion urography had shown that obstruction was not complete. Other radiographs showed that extreme dilatation of the ureters did not necessarily prevent them from emptying themselves actively. In some cases the irritation of the pelvis by the fluid introduced in instrumental urography had prevented the filling of one or more of the calyces, and so gave a false idea of the condition of the kidney; the substances used for excretion urography, being non-irritating, filled calyces which were invisible by the older method. Tuberculosis, Dr. Hughes said, often prevented the introduction of the cystoscope or ureteric catheter; excretion urography showed both the anatomical and the functional disability of the kidney; if the lesion was sufficiently advanced no excretion took place, and the kidney was not visible. In tuberculous disease of the adnexa in men a curious appearance was sometimes found; the shadow of the ureter ended abruptly just before it should have entered the bladder, and a condensation of the contrast substance was seen at the site of the apparent obstruction; there was no dilatation of the pelvis, however, and the condition was no contraindication for removal of the other kidney. Excretion urography was especially valuable in estimating the importance of ureteral changes. Kinks in the ureter, for example, when due to fixation, appeared in the same place in successive pictures; ureteral catheterization made it difficult to assess the importance of such deviations, and it was possible to overlook a fix[illegible] he ureter which was giving rise to [illegible]acks of [illegible] n if this method only was used. W[illegible] [illegible]es due to ascending infection from [illegible]natic or prostatic abscess were well shown by [illegible]etion method. The chief value of the newer [illegible] lay in the insight which it gave the surgeon into [illegible]iology and pathology of the urinary tract; it [illegible] a new field of therapeutic progress by defining [illegible]ne for conservative treatment and for surgical [illegible]. The importance of D. 40 as an agent in [illegible]raphy lay in its non-toxicity, its rapid and [illegible]mination, and in the small dosage in which only 20 c.cm. of the solution being used

In cases showing [illegible] tension [illegible] be of value [illegible] meningo-encephalitis [illegible] the stiff posit[illegible] dilutions of serum [illegible] occurs; consequently [illegible] after thorough mixing

Mr. FRANK KIDD, in thanking the speakers, said that the Section was honoured in being the body chosen by Professor v. Lichtenberg to hear his first official pronouncement on his work with the new contrast substances. Besides being the inventor of the method of ascending pyelography, Professor v. Lichtenberg was the first person to produce an effective technique in excretion urography. Mr. Kidd understood that D. 40 would shortly be placed on the market.

TONSILLECTOMY AND RHEUMATISM

At a meeting of the Liverpool Medical Institution on Thursday, March 19th, with Mr. G. C. E. SIMPSON, vice-president, in the chair, Mr. P. W. LEATHART read a paper on the value of removal of tonsils and adenoids in subacute rheumatic heart disease.

Fifty in-patients at the Liverpool Heart Hospital were chosen for operation. All suffered from fever for a long period before operation, and had one or more cardiac lesions. The reason for operating was based on the assumption that the patient was a "carrier" of the infection in his tonsils and adenoids. The speaker pointed out that the size of the tonsil was not important. The presence of enlarged glands in the anterior triangle of the neck was considered to be of more importance, inasmuch as it was clinical evidence of absorption of poison from the tonsils into the lymphoid system. Removal of the tonsils could not do more than prevent further absorption from them. The results of the operations were tabulated after the patients had been under observation for periods in some cases as long as four years, and gave the following statistics:

1. In 16 cases the temperature finally became normal and stayed normal.
2. In 20 cases the cardiac condition became stationary.
3. In 8 cases there was improvement in the cardiac condition.
4. In the rest it was impossible to give an opinion.
5. In all cases except one the relatives were emphatic that the general health had improved.

The fact that improvement took place in some cases after operation opened up the question of the physiology of the tonsils. Were they "front line" barriers to infection, or were they open doors for the purpose of admitting disease elements? The latter view was the more reasonable, for they knew that all tonsils and other external lymphoid masses, such as Peyer's patches and solitary follicles, contained organisms even in healthy subjects. It was probable, therefore, that in health poison was being absorbed from the tonsils, the object being to establish or to keep up immunity. If the immunity was at a low ebb or was failing, more poison was being absorbed than could be dealt with, and the patient was in danger. In such cases, if there was evidence (such as enlarged cervical glands) that the tonsil was allowing poison to enter the blood, the tonsil should be removed.

In the discussion which followed Mr. COURTENAY YORKE made a plea for a more conservative attitude with regard to the tonsils. He considered that local infection in the tonsil was a very uncommon cause of systemic disease, and he believed that the tonsils were sacrificed far too often from the mistaken view that they were centres of auto-infection. He pointed out that the tonsil crypts were lined by stratified epithelium, which afforded an effective barrier to infection. The presence of cheesy material in the follicles was very common, and could not be regarded as pathological. The operation of tonsil dissection, under a general anaesthetic, in adults, was a severe one, and fraught with obvious dangers. It should therefore be performed advisedly at all times, and especially in the type in which the condemnation of the tonsils was based on the supposition of auto-infection.

Mr. H. V. FORSTER remarked upon the physiological and protective function of the lymphadenoid tissue of the pharynx and post-nasal space. They were on common ground in recognizing the importance of that aspect, but might not yet be in full agreement concerning the lecturer's view that these areas were open doors through which the individual invited combat and was content to prove victorious or to be eliminated on the result of the fight. It would be better if the invader were fought in a front line engagement, rather than that a serious conflict be allowed to occur with the more deeply placed reserves; and it was interesting to know that Kaiser had recently recorded that in a large group of American children, deprived by operation of the familiar masses of lymphadenoid tissue of the upper respiratory and food passages, there was shown a greater incidence of bronchitis and pneumonia than in controls.

Dr. I. HARRIS pointed out that the danger of operating on these cases was exaggerated. As long as there was no grossly damaged heart muscle the cardiac patient usually stood an operation as well as the patient whose case was uncomplicated.

Mr. E. MALCOLM STOCKDALE considered that the structure of the tonsil was such that it constituted a weak spot, readily becoming infected, and apt to disseminate disease. Few individuals escaped an attack of tonsillitis. As the treatment of adenoid and tonsil disease had progressed, the number of cases of enlarged tuberculous glands in the neck had greatly diminished, as had also Pott's disease of the spine. The size of an infected tonsil was no indication of its power for evil, a small red buried tonsil being more dangerous than the greatly enlarged pale protruding tonsil.

INHALATION ANAESTHESIA

Dr. R. J. MINNITT read a paper describing a new technique in the administration of inhalation anaesthesia, with some biochemical comparisons. He said that he had examined in detail different forms of anaesthesia, having regard to the removal of the patient's discomfort during induction, the allowance of maximum surgical approach through satisfactory relaxation and tranquillity of abdominal viscera, and the minimum amount of post-anaesthetic toxaemia and damage to the organs of elimination. He described the McKesson-Nargraf apparatus by means of lantern slides, and explained the technique of inhalation anaesthesia both with the face mask and with de Caux's intratracheal catheters. Particular attention was paid to rebreathing, and to the small amount of ether used with the machine. He had had experience in over two hundred cases, including almost every kind of operation. The advantages were comfort and speed of induction, the minute quantities of ether used, absence of cyanosis, speedy recovery, reduction of post-anaesthetic vomiting and taste or smell of ether, and the freer atmosphere in the operating theatre from ether exhalations. Tables were presented showing the influence on blood sugar of the open ether method, and the effect of the anaesthetic on the carbon dioxide of the blood and on the blood urea. The evidence was much in favour of rebreathing, the addition of carbon dioxide to the anaesthetic gases, and the elimination of ether as far as possible in kidney disease.

In the discussion which followed, Dr. JOHN HALTON thought that the success or failure of any anaesthetic depended largely upon the patient's condition immediately prior to induction. He had recently perfected a technique which, for open ether anaesthesia, required the average use of only 8 to 12 ounces of ether for the first hour of major operations. In roughly 300 recent anaesthetics administered in this way as hospital routine, compared with 100 by ordinary methods, the difference in post-operative comfort and absence of complications was very marked. Mr. H. C. W. NUTTALL thought that if the method described by the lecturer was found to be superior to other methods in hospital, its use must be extended to private practice; here its cost and the bulk of the apparatus were difficulties. He did not agree that it should be reserved for specially difficult cases, routine use with all types of case being essential for perfecting technique.

CERVICAL CARCINOMA

A meeting of the Edinburgh Obstetrical Society was held on March 11th with the president, Dr. H. S. DAVIDSON, in the chair. Mr. HENRY WADE and Mr. DAVID BAND contributed a paper on the cystoscopic appearances in carcinoma of the cervix uteri, including in their remarks a consideration of the advantages which might be gained by intrasigmoid transplantation of the ureters.

The reports of two necropsies were quoted as illustrative of the end-results of extension of carcinoma of the cervix to the urinary tract. In the first case, the carcinoma had involved the bladder and one ureter, with atrophy of the kidney above. A vesico-vaginal fistula was present. Death had resulted from ascending infection and pyelonephritis of the remaining kidney. In the second case, the neoplasm had extended from the cervix and had involved the ureter at the base of the broad ligament. Atrophy of the kidney had resulted. Death was caused by renal suppression and anuria, the result of disease of the remaining ureter.

A fatal issue in carcinoma of the cervix was frequently brought about by one of the following complications: (1) renal infection—(*a*) ascending pyelonephritis, (*b*) blood-borne pyelonephritis; (2) renal suppression. As radium therapy had now superseded radical operation in the treatment of the majority of cases of cervical carcinoma, the information obtained from the use of the cystoscope was of considerable importance if the extent of the disease was to be accurately determined. The effect of radium on healthy as well as on neoplastic tissues rendered it essential that due attention be paid to the neighbouring organ as a guide to technique, dosage, and prognosis.

Involvement of the bladder from anterior extension of carcinoma of the cervix might be recognized in six stages, of increasing gravity—namely, elevation of the bladder floor, fixation of the bladder floor judged by digital manipulation of the cervix, circulatory changes, transverse ridge formation, oedema, and malignant invasion. Of these the first three were those associated with any retro-vesical collection or swelling, and as such might be produced by radiation of a cervical carcinoma, although the bladder was unaffected by malignant disease. The condition of the ureteral orifice was most important, as it was the earliest guide to the diagnosis of involvement of the lower urinary tract; in a series of cases in which spread of the cervical carcinoma was taking place the first changes in the bladder were noted at the openings of the ureters. The appearances of the ureteral orifice were, in order of gravity: (1) fixation, (2) retraction, (3) circulatory changes, (4) irregular gaping, (5) ulceration and nodule formation. It was found that the general health of many patients remained excellent for over eight months before mechanical interference of the excretion of urine brought about renal incompetence.

By the operation of intrasigmoid transplantation of the ureters, total vesical exclusion could be carried out with safety, and following the operation the patient had comfort and complete urinary control. The lesion in the pelvis might then be attacked with renewed hope, and radiation or radical surgery might be directed entirely to the carcinoma, without limiting the efficacy of the method by allowing for the protection or preservation of components of the urinary system.

Reviews

BURNS

In 430 B.C. Hippocrates advised for the treatment of burns "molten old swines seam mixed with resin and bitumen," a formula curiously suggestive of the olive oil, resin, and asphalte constituents of the modern paraffin applications for the same condition; and so comprehensive is the American publication *Burns: Types, Pathology, and Management*,[1] by G. T. PACK and A. H. DAVIS, that both of these treatments, chronologically so far apart, are mentioned. The whole book indeed, with its short excursions into the historical side, emphasizes the significance of the authors' quotation from St. Jerome, "Perish those who have said our good things before us." Thus we find that in 1864 Lawson Tait advised melted paraffin, the efficacy of which had been noted in 1854 by Nelaton, while in 1842 Curling read a paper before the Royal Medical Chirurgical Society upon the occurrence of acute duodenal ulceration in burns, a complication also previously noted by Dupuytren and Cooper in 1832.

The book is divided into three parts; the first deals with the anatomy, physics, and pathology of burns. In this section it is noted that there are 7,000 deaths yearly in the United States of America from this cause, and that the death rate is 7.0 per 100,000 as compared with 15.0 for appendicitis—adequate reason, if any were needed, for the appearance of a monograph upon the subject. The blood and tissue changes are described fully, but the nature of the toxaemia, which is one of the commonest causes of a fatal ending, remains completely obscure, as is indicated by the formidable list of some twenty-four possible substances. Until this biochemical problem is solved there can be little hope of treating the toxaemia upon any other than general lines, and, of these, infusion with a glucose-saline-insulin solution is very strongly advocated upon both a theoretical and an experimental basis. The incidence of duodenal ulceration is given as about 6 per cent., but this figure is obtained from rather old statistics, and it is not mentioned whether the newer forms of treatment have produced any diminution.

The second section deals with the management of thermal burns, and includes a complete summary of practically every form of treatment and application that has been devised. There can, however, be no doubt about the authors' preference for the tannic acid method introduced by Davidson of Detroit, which they consider gives better results than the paraffin spray or dusting with zinc stearate. Few who have had experience of the method will be inclined to disagree with their conclusions, for, although good results have been obtained by both the other methods, there is a certainty, ease of application, and absence of complications about the tannic acid treatment which renders it now the method of choice. Picric acid, aluminium acetate, acriflavine, and a host of other watery antiseptic applications are condemned upon logical grounds, and although the theoretical arguments used in favour of tannic acid as opposed to other occlusive dressings are perhaps not convincing, yet there can be little doubt concerning the superiority of the practical results obtained. This section includes also chapters upon the care of granulation tissue, skin grafting, and plastic work in the correction of deformities following burns. It is interesting to notice, in view of the recent treatment of varicose ulcers by complete enclosure in strapping without exit for discharges, that this method was advocated by Parker in 1915 for the preparation of large burned areas, to reduce their size and as a preliminary to skin grafting. In this chapter a curious case is recalled in which L. Frazer (*British Medical Journal*, April 1st, 1905) used Thiersch grafts from a rabbit which, transplanted to a burnt area on a child's chest, took and grew a "soft fur." Despite the date under which this case was reported, and the fact that it does not agree with general ideas about heterogeneous grafts, it is certain that the tissues of the rabbit can be grown upon human plasma *in vitro* (N. C. Lake: *Lancet*, October, 1917; *Journ. Physiol.*, September, 1916). The chapter upon reconstructive operations is largely founded on the plastic work of Dr. Sheehan, and indicates graphically what results may be expected. The final section is devoted to regional burns, and those caused by specific agents, including radium, *x* rays, war gases, etc., and each of these chapters is more than adequate.

Altogether this is a very instructive book, well-illustrated and well produced, giving the practitioner who may be called upon at any moment to deal with a severe burn—and this applies to all—a good idea as to the best method of treatment from the earliest to the latest stages.

CLINICAL CHEMISTRY

In the preface to their book *Clinical Chemistry in Practical Medicine*,[2] Drs. C. P. STEWART and D. M. DUNLOP indicate very accurately its scope and aims. In brief, they say that it is meant to give information to the practitioner, the house-physician, and the senior student about the part played by chemical methods in the diagnosis and treatment of disease.

The problem which the authors have set themselves, and in which they have in the main succeeded, is one of selection. They have inevitably been faced, all along, by the problem of what to leave out. The subject is already so large that wholesale inclusion, whether of methods or of theories, is clearly out of the question. The selector's task is always an invidious one, and it is certain that his readers will be prepared to quarrel with him from time to time, no matter how nice his judgement; but on the whole Drs. Stewart and Dunlop may hope to escape lightly. Their plan of campaign has, however, laid them open to certain criticisms; for example, they have devoted a good deal of space to the description of methods, doubtless with the intention of familiarizing their readers with the way in which relevant information may be obtained and the standards of accuracy attainable in given circumstances. Yet their descriptions are necessarily cut as short as possible, and, in consequence, are not detailed enough to serve as laboratory guides for the actual performance of the tests. In these circumstances, are they really worth giving at all? Those familiar with laboratory technique will realize their inadequacy and go elsewhere; those who are without laboratory experience will "skip" the passage, since they will be unwilling to burden their memories with data that, to them, are more or less meaningless. However, faced with the twofold difficulty of compression and selection, perhaps the authors had little choice open to them. There is no doubt that the book contains very much that is of value, while the clear and definite style in which it is written will commend itself to all readers.

A few passages are open to criticism of a less general kind. In the section on the CO_2 combining power of the blood, phosphates are cited as one of the three important buffering mechanisms concerned. Now there are about 4 mg. of phosphorus per 100 c.cm. of blood, and only

[2] *Clinical Chemistry in Practical Medicine.* By C. P. Stewart, M.Sc.Dunelm, Ph.D.Ed., and D. M. Dunlop, M.D., M.R.C.P.Ed. Edinburgh, E. and S. Livingstone. 1930. (Pp. ix + 246; 24 figures. 7s. 6d. net.)

part of this is inorganic phosphate. Even if it all represented inorganic phosphate, it would be capable of providing alkali to combine with only about 2.9 out of the 40 to 60 c.cm. of CO_2 carried by 100 c.cm. of blood. The important part played in the process by haemoglobin does not, on the other hand, receive specific mention. In discussing bile formation, the authors do not mention the recent work of F. C. Mann and his collaborators, which brought out the interesting suggestion that the bone marrow of the long bones was an important site of pigment formation. In the description of the glycerophosphate test for renal efficiency, the authors should have shown more clearly that it is the esterase activity of the organ that is being investigated. On the other hand, the section on fractional test meals is admirably clear, and the specimen charts are most instructive.

EPIDEMIOLOGY

The principal difficulty of a reviewer who wishes to be just, both to his author and to the public, is that praise is easily given in a few words, while blame, unless it is merely arrogant, must be accompanied by detailed reasons. Hence the risk that, in the limited space of a review, blame may predominate although the reviewer may wish to convey a favourable impression of the book as a whole. In writing on Dr. STALLYBRASS's book on *Epidemiology*,[2] the reviewer feels this difficulty acutely. A good deall of the book seems to him so good that he would be sorry to deter any reader from studying it, but at the same time he thinks that the medical officer of health—for whom the book is specially written—who reads it straight through will be frequently puzzled and sometimes misinformed. Perhaps the fairest thing to say is that if the medical officer of health will begin at Chapter VII and go straight on, skipping all excerpts from mathematical papers and equations, he will have read an excellent treatise, containing not only some original contributions to science, but a good summary of investigations not readily accessible to the ordinary English reader. The chapters on alimentary infections and on aggregation and dispersal are particularly good, and would alone suffice to justify the existence of the book. Indeed, if reduced to the 450 odd pages mentioned, the treatise could have been commended with few reservations.

Unfortunately, Dr. Stallybrass has thought it his duty to write on topics really outside the scope of his undertaking. "Epidemiology," he says, "is the science of the infective diseases—their prime causes, propagation, prevention. More especially it deals with their epidemic manifestations." This is a faulty definition. The first sentence includes much that is not epidemiological, and excludes something which is, while the second is merely circular reasoning. Epidemiology is concerned with the study of disease as a herd phenomenon; it takes as the unit of observation a group, not, as does clinical medicine, an individual. Whether the disease in question is "infectious" or not does not arise. But the faulty definition would not have mattered—in the good parts of the book the proper point of view is adopted—had not Dr. Stallybrass made the further mistake of supposing that because knowledge of a particular kind is useful to an epidemiologist, therefore the teaching of it ought to be included in a treatise on epidemiology. He has devoted many pages to subjects which no more belong to epidemiology than does German grammar. A knowledge of statistical methods and of the principles of bacteriology and immunology is desirable—indeed, essential—for an epidemiologist, but so is a knowledge of German. Dr. Stallybrass has not, however, provided a table of the German irregular verbs, but he has provided longish chapters on subjects quite adequately treated in accessible English textbooks, and these chapters, particularly that on statistical methods, are not satisfactory. For example, the italicized passage at the top of page 66 betrays a misconception of how "spurious" correlation arises, and of how, if desired, it may be eliminated, while the worked example of correlation on page 70 is faulty. Dr. Stallybrass had the less excuse for writing on subjects which he has not mastered inasmuch as the good parts of his book demonstrate what valuable information he can convey without going outside the sufficiently wide field of his own knowledge.

It will be seen that, as feared, unfavourable criticism has taken up more space than commendation, and the reviewer desires to end on another note. He thinks that the positive merits of the book outweigh its defects, and that a judicious reader will have cause to be grateful to Dr. Stallybrass, who can teach him much well worth knowing.

HISTOLOGY FOR MEDICAL STUDENTS

Students of normal histology will find HARTRIDGE and HAYNES's *Histology for Medical Students*[4] a most useful handbook for reference in the course of their practical work. The information contained in it, so far as human anatomy is concerned, is very complete, and the student will meet with few difficulties in his work, both with regard to technical details and in the interpretation of his sections, which a reference to its pages will not clear up. The descriptions are short and to the point, and the essential characters of the tissues are explained without burdening the descriptions with details that only specialists would require. With few exceptions the tissues of the body are depicted by means of coloured figures, which, although small and in many instances semi-diagrammatic, have been made by the authors themselves with the aid of the camera lucida, and are well chosen and accurate. The figures number more than 500, and it is evident, therefore, that almost every anatomical statement in the text receives pictorial illustration. The sections on microscopical technique are excellent, and include the principles of staining, microscopical tests, section cutting, micro-dissection and injection, grafting and tissue culture, blood counts, intravital staining, photomicrography, and the general management of the microscope. The functions of the tissues are in many cases referred to, and, where necessary, the embryology is described. A short but important section is devoted to a matter which the student is apt to neglect—namely, the proper method of diagnosis. Two methods of identifying tissues are described, which may be termed respectively the method of "recognition without reason given," and the "analytical method," the former depending on familiarity with the tissues, which are recognized as soon as seen, the latter on a systematic study of the constituent elements and their arrangement. The latter is the method which will be indispensable to the student in his later pathological work, in which a "lightning diagnosis," although brilliant, is always dangerous. The book is provided with a very good index—a matter of some importance in a work of this kind. The microscopical sections used for furnishing the illustrations are from those given out as routine specimens to the class in histology, and they convey a very good idea of the thorough grounding in normal histology which is offered to the student in these days.

"THE MATERIALS OF LIFE"

The interest of the intellectually minded section of the non-scientific public has of late years shifted away from the biological and towards the physical sciences. The situation is in sharp contrast to that which prevailed in the latter part of last century, when the influence of Huxley was still dominant. The change can be easily understood. The mechanical sciences have been responsible for most of the more recent and striking developments of civilization; not only this, but it must be a dull mind indeed that is not stirred and fascinated by the stories which the modern worker in atomic physics can unfold. Biology, on the other hand, while progressing probably with equal rapidity, has nothing so spectacular to show: the most interesting fields of modern biological research cannot be easily appreciated without at least some scientific discipline. It is undoubtedly beneficial to the individual layman to take some interest in biology. For one thing, a little learning, far from being a dangerous thing, may easily save him from some very silly blunders. However, to help him over the preliminary stages, there is a real necessity for the right sort of popular book and newspaper article. Of such a kind is T. R. PARSONS's *The Materials of Life*.[5] It is eminently readable, and is written in a very easy and pleasant style. It covers quite a wide ground; while dealing primarily with biochemistry, it touches on many of the fundamental facts of biology. It is chiefly concerned with the human body, but the author's interpretation of his scope is by no means narrow. The book is really interesting and informative; it puts before its readers the more important and fundamental facts concerning their own bodies and their food without that lamentable atmosphere of prejudice and propaganda that destroys the value of too many "popular" books.

NOTES ON BOOKS

The useful volume on *General Medicine*[6] in the Practical Medicine Series (1930) consists, as in previous years, of five parts, devoted respectively to infectious diseases, diseases of the chest (excepting the heart, but including tuberculosis), diseases of the blood and kidneys, diseases of the heart and blood vessels, and diseases of the digestive system. The editors of the different parts are the same as last year (see *Journal*, 1930, i, 548).

We have received the first four numbers of *Nosokomeion*,[7] or Quarterly Hospital Review, which is published at Stuttgart under the editorship of Geheimrat Dr. W. Alter of Düsseldorf, assisted by E. H. L. Corwin of New York, A. Gouachon of Lyons, R. H. P. Orde of London, and R. Sand of Paris. Papers are published in English, French, or German, followed by a brief summary in two languages. Among the twenty-four papers—fifteen of which are in German, seven in English, and two in French—published in the present volume, we may draw attention to the following: "The hospital with a soul," by Dr. E. H. L. Corwin, general secretary of the International Hospital Committee; "What can European and American Hospitals learn from each other?" by Dr. W. H. Mansholt, medical superintendent of the general hospital at Groningen; "Occupational therapy," by Mr. T. B. Kidner, president of the American Occupational Therapy Association; "The legal aspects of the patient and the hospital," by Dr. Alexander Philipsborn of Berlin; and "The new possibilities of hospital treatment of malignant tumours," by Mr. J. Courtney Buchanan, late honorary secretary of the British Hospitals Association.

The fourth edition has now been published of Professor LOGAN CLENDENING'S *Modern Methods of Treatment*.[8] It is little more than a year since we reviewed the third edition. The general plan and purpose of the book have not been changed, but a good deal of new matter has been added here and there, and "several mistakes which, as Horace Walpole said, indicated that it was the work of a gentleman rather than of a mere scholar, have been corrected."

Ionization and its Medical Applications,[9] by Drs. P. DUHEM and J. DUBOST, opens with a short account of the physics of electrolysis, and the greater part of the volume is devoted to its therapeutic applications. Perusal of the work shows that French theory and practice differ in many respects from the current teaching in this country. For example, electrolysis with lithium salts is recommended for the treatment of gout, and the treatment of hemiplegia by electrolysis of calcium salts is discussed at some length.

The proceedings of the Third Congress of the World League of Sexual Reform,[10] which was held in London last September, under the presidency of Dr. Magnus Hirschfeld of Berlin, have recently appeared. The communications, of which there are over 120, deal mainly with the reform of marriage, birth control, sterilization, the censorship of literature and films, sexual education, and rejuvenation. They will no doubt be read with interest by many students of social hygiene.

The history of "The Ginepathic Institute Free Hospital," which, after several changes of title, became the Samaritan Free Hospital, and as such was made famous throughout the world by Spencer Wells, is well told by Dr. ARNOLD WHITAKER OXFORD in a small booklet.[11] Started in 1847 in Gray Street, Manchester Square, the early minutes of its committee amply explain the prejudices against special hospitals, which were so strong in the profession and in the medical press at that time. Like a few other institutions, the Samaritan outlived the defects of several of the members of its staff and committee, and some of the practices which, to the present-day reader, seem to be almost incredible.

PREPARATIONS AND APPLIANCES

SURGICAL GLUE

Major MEURICE SINCLAIR, R.A.M.C. (ret.), writes: On account of frequent requests, Messrs. Bell and Croyden, 50, Wigmore Street, London, W.1, have put up in a very convenient carton "Sinclair's glue," for extension, etc. Inside is a brush and screw-top aluminium box, which contains a correct measure of this preparation in a new, powdered form. They have sent me several samples for trial, and I have found it of pleasant odour, very tenacious, exceedingly strong, and translucent; it dries effectually without getting brittle, may be indefinitely stored, and can be exported to damp climates abroad. It can also be sterilized. Each carton contains a sufficient quantity of the adhesive to apply extensions to about six limbs. When the glue is required for use, cold water is simply added up to the lowest thread of the screw on the box, and the latter is then put into a pan of water, which is made to boil. When the contents are dissolved, with the aid of little stirring, the glue is ready for use, ordinarily within 10 minutes. The outfit is very practical.

INVESTIGATION OF MATERNAL MORBIDITY

Queen Charlotte's Research Laboratories

Queen Charlotte's Maternity Hospital is gradually bringing to completion, on its site of five acres in West London (at Ravenscourt Gardens, Shepherd's Bush), the most comprehensive obstetric unit in the country. Some account of the general plan was given in the *British Medical Journal* of July 19th, 1930 (p. 118). The isolation block for infected cases has been built, and plans have been completed for a great building with 200 public beds, a labour ward unit, a private block of 80 to 100 beds for paying patients, an out-patients' block, an administrative block, a students' college, and a nurses' home.

The block containing the pathological laboratories was opened recently for inspection, when the arrangements of the building and the projected programme were described by Dr. Leonard Colebrook, who was for some time honorary pathologist before the isolation block was erected, and is now director of research. The Medical Research Council, fully alive to the importance of the investigation into maternal mortality and morbidity, is providing the whole-time services of Dr. Colebrook and Dr. Ronald Hare.

The Pathological Block

The laboratory block is separate from, but in close connexion with, the isolation hospital and its auxiliaries. It is a three-story building, the ground and first floors containing the laboratories, and the second floor stores and offices. The construction and finishing is on the most modern lines. The heating system, for example, is on the unusual principle of heating from above downwards; the radiators are installed behind cast-iron ceiling panels, all easily removable, and the panels in each room are separately controlled, so that the heat can be regulated to a nicety. Ventilation is assisted by fanlights over the doors, controlled by a novel form of gearing. The general lighting is by means of opal ceiling lamps and special wall fittings adjustable to any desired vertical or horizontal position by means of elbow-joints. Internal drainage is by means of wide untrapped porcelain piping.

The first of the series of laboratories is for routine pathological work. All the investigations necessary to a bacteriological diagnosis of every case admitted to the isolation hospital are carried out here, and a report on the case is available at latest on the day following admission. In the histological laboratory sections of tissue are cut to a thinness of approximately 1/2000th inch, and examined; and in the biochemical laboratory the work to be done includes the differentiation of bacterial species by chemical means, the search for substances for checking puerperal infections at the beginning—Dr. Colebrook indicated metarsenobillon as offering the most hopeful line in this respect—and investigation into the toxaemias of pregnancy. An inoculation room is also on the ground floor, and there is a balance room, where special provision has been made to keep balances free from dust and immune from shocks.

Bacteriological Research

On the first floor are situated the two best laboratories in the block. These are for bacteriological research, and here the problem will be investigated as to why it is that even in perfectly normal confinements some women pick up the micro-organisms of puerperal fever. It is hoped to elicit whether there are only a limited number of strains of streptococci which are particularly dangerous to women at childbirth, to work out better methods for the final differentiation of these strains from others not so dangerous, to discover whether it is possible by the inoculation of a vaccine so to stimulate the defensive mechanism of the mother during the later weeks of pregnancy as to enable her to overcome infection, and to investigate the possibility of preparing a serum which will afford protection against a large number of dangerous strains. Other rooms are an incubator room, which is steadily maintained at body heat all the year round, a dark room for photographic purposes, a refrigerator, and a still-room, where provision is made to exclude contamination of cultures by dust. There is also what is known as the "medium suite," where the culture medium is prepared. The laboratories have been equipped with much special apparatus. One device is a modern centrifuge, making 3,000 revolutions a minute, for separating bacteria from the liquid medium in a test tube, a result which it accomplishes in about a quarter of an hour, whereas many hours would be required if the method of settlement by gravity were adopted. An electric blower for sealing off glass tubing, enormous quantities of which are required, is also installed, and another interesting apparatus is the Mackintosh-Fildes jar, providing the oxygen-free condition essential for the cultivation of anaerobes.

The unit is extremely well furnished, and Dr. Colebrook claimed that it was the first complete unit in the world for tackling its problem. At the same time he said that only three people were engaged in the research, and if the requisite funds were available a chemist and two more workers could be advantageously employed.

ROYAL MEDICAL BENEVOLENT FUND

At two recent meetings of the committee of the Royal Medical Benevolent Fund, seventy-seven grants, amounting to £1,779 4s. 8d., and forty grants, amounting to £947 10s., were voted, making a total of £2,726 14s. 8d. during the first two months of this year. Of this sum £2,218 was distributed as maintenance grants among ninety-two beneficiaries whose incomes, being so small, required extra help in order that the necessities of life might be obtained. The balance was given to some who had broken down in health and to others who were in temporary difficulties.

Subscriptions and donations are urgently needed in order that the activities of the Fund may be continued, and applicants given the help which is so very sorely needed. Cheques should be forwarded to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, W.1.

The following are particulars of a few of the cases recently helped.

M.R.C.S., L.R.C.P., aged 75. Suffering from malignant disease of the prostate, and has for many months been bed-ridden. The applicant and his wife, who is worn out by nursing him, were found to be living from hand to mouth in very straitened circumstances. The local medical society has made a collection among its members to assist this old couple. Voted £45.

M.R.C.S., L.S.A., aged 76. Applicant gave up practice after thirty-eight years of work owing to ill-health. His practice was not a lucrative one, and he brought up and educated six children, one of whom qualified in the medical profession. Owing to his heavy family expenses his savings on retirement were very small, and he and his wife are practically penniless. The couple are now boarding with a son, who is an electrician earning £300 a year; this extra burden has thrown the son into debt. Voted £45.

M.R.C.S., L.R.C.P., aged 67. Suffering from aortic disease and unable to work. The capital saved after thirty years of work was lost through a business failure. Relations are contributing £100, and the wife has a private income of £25. Voted £40.

Widow, aged 63, of M.B. The husband died in 1895 at the age of 28, when he was a medical missionary. Since then the applicant, by her own industry and efforts as a hospital nurse in England and Australia, as matron in a school in Canada, and finally as secretary to a society in England, has maintained herself. Ill-health has now forced her to resign and to give up all active work; she has an income of only £60. Voted £26.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, Tavistock House (North), Tavistock Square, W.C.1.

British Medical Journal

SATURDAY, APRIL 11th, 1931

TECHNICAL OFFICERS IN GOVERNMENT DEPARTMENTS

The British Science Guild is a voluntary society, non-political in character, whose object is to promote the application of scientific methods and results to social problems and public affairs. It has submitted evidence to the Royal Commission which is now considering the structure and organization of the Civil Service. The memorandum of this evidence, and the larger report[1] on which it is based, embody observations and opinions which are of much importance and interest to the medical profession, as to others. They deal with the position of the scientific and professional staffs in the public services, viewing this position, not as a matter of class grievance, but as a national imperfection. The committee of the Guild responsible for these documents contained only one medical member, Sir Arthur Newsholme; and there is but little explicit or specific reference to medical matters in them. It may be a fact that the position of the medical staffs of some Government departments is less unsatisfactory than that of other scientists and technicians. The principles stated, and the suggestions made, by the Guild are, however, of general application, and with some of them, at least, the medical profession will certainly wish to associate itself.

When the permanent Civil Service was first established its organization was appropriately such as had reference to the purely administrative, fiscal, and clerical duties it had to perform. Later it was found that certain specialized scientific and technical matters, as distinguished from simple administrative problems, had to be handled by the departments, and a small number of professional experts, usually acting in a purely consultative capacity, were introduced into the staff organization, where they occupied a subordinate position. Of recent years there has been a great enlargement in the sphere of Governmental activities; the work of the professional, scientific, and technical members of the Service has grown in value and importance; the character of this work has largely ceased to be merely advisory; and there have even been established separate departments of scientific, industrial, and medical research. Yet with all this the position and status of technical members of the staff relative to that of the purely administrative members has scarcely changed. The Guild points out that "officers of the administrative class continue to dominate the whole situation in the State departments. . . . The methods of organization are such that the technical experts, instead of occupying positions giving them direct access to Ministers, are, as a rule, subordinates of the permanent head of the department. Sometimes they are subject not only to the control of a single administrator, but also to that of clerical officers of the secretariat. This sometimes leads to the usurpation by non-technical officers of the proper functions of the professional and technical groups." This often results in the Minister being provided only with a layman's interpretation of the expert's advice, or, on occasion, in the suppression of some technical reports altogether. In view of this position it is essential, in the opinion of the British Science Guild, that "the Civil Service should now be organized internally so as to enable those having the best available knowledge in any department to take a full share in the formation of policy, and to have the right of access on major issues to the controlling administrative authority and the Ministers," and that there should be "a system of Boards on which the experts would serve on equal terms with the administrators." The principle underlying these contentions is one which, in its relation to public health administration and the medical side of other Government services, may well receive the support of the medical profession.

With regard to further recommendations that "the essential unity of the professional, scientific, and technical services should be recognized by treating them as a single national technical service," and that "the fullest opportunity should be given to specialist officers possessing administrative gifts to rise to the highest administrative posts, including the permanent secretaryships of the larger departments," there may be less unanimity and greater difficulty. Certainly the classification and systematization of the professional and technical staffs might well be made simpler and more uniform, and there may be occasions on which the head of a technical department, by reason of great administrative ability, should be appointed a Permanent First Secretary. It is more than doubtful, however, whether he should continue to exercise the duties of both offices.

In this connexion two other points may be mentioned which are not referred to by the British Science Guild. It has lately been contended that the technical sections of Government departments should be reduced to a minimum, and that most of their work should be given to private individuals or firms. This does not seem to be a feasible proposition, at any rate as regards matters of public health and medicine, but even in that sphere the employment of part-time officers for suitable purposes may well be encouraged, and it is possible that other Government departments sometimes undertake work which might preferably be done elsewhere. The second point is that in association with any professional group in a Government office it will usually be found advantageous to have a small advisory committee of representatives of the whole profession concerned. Such a committee is established—perhaps it would be more correct to say that such committees are established—at the Ministry of Health in relation to the medical

[1] Report on the Scientific and Professional Staffs in the Public Services and Industry. The British Science Guild, 6, John Street, Adelphi, London, W.C.2. (1s.)

profession ; and though there may be periods during which the activities of such a committee seem of little importance or effect, yet it continuously serves as a useful means by which the official department can be kept in touch with the daily work and the organized opinion of the whole profession, of which the official technical group in the Civil Service forms a part.

TENDON RUPTURES

Mr. Harry Platt's lecture on this subject to the Students' Medical Society of the University of Leeds, on which is based the paper printed in this issue at page 611, contained a great deal that is of practical surgical value and importance. Such accidents are not dangerous to life, but the resulting disabilities, if not properly treated, may cause lifelong inconvenience or even crippling inefficiency. The injuries referred to range from the tendons of the fingers to that of the triceps cruris, the largest and strongest tendon in the body. Cricketers in this country, and baseball players elsewhere, are familiar with the dropped finger which follows a maladroit attempt to catch a hard-hit ball ; and among sufferers from rupture of the tendo Achillis there have been distinguished surgeons who have described the injury in their own persons and their treatment of it. Such were Munro Secundus of Edinburgh, John Hunter, and, in our day, Sir John Lynn Thomas.

Early diagnosis and prompt treatment of these injuries are greatly to be desired, but it is reassuring to find from Mr. Platt's statistics that even long-deferred operative treatment of such a serious injury as total rupture of the tendo Achillis can be so successful as it has proved to be in his hands. Nine out of the ten cases on which he operated enjoyed perfect function as an end-result, and the remaining case had "good function." These results were obtained by suture and in some cases by grafting of fascia or tendon. They are all the more satisfactory because, strange as it may at first sight seem, complete rupture of the tendo Achillis has, in many recorded cases, escaped detection until weeks have passed. Such oversight is due to the amount of effusion and oedema which follows immediately after the injury, but should not occur if the surgeon has in mind the fact that careful examination is necessary in all disabling injuries. Ruptures which, if promptly diagnosed, could be satisfactorily treated by means of simple suture, may, when left untreated for weeks, require extensive and bold operations. For example, in one of Mr. Platt's cases he used both the peroneus and the tibialis posticus tendons to bridge the gap left by retraction and atrophy. It is fortunate that dropped finger is easily recognized, because open operations for this injury are seldom successful.

The best known of the spontaneous ruptures of tendon is that of the extensor longus pollicis, either associated or not with fracture of the lower end of the radius, and usually following painful tenosynovitis. In such cases success in restoring function will not be attained unless the obliquity of the tendon is preserved. In order to secure this, Mr. Platt adopted successfully the device of a loop or pulley formed from a piece of free fascia. Ruptures of the long tendon of the biceps brachii at its upper part are not uncommon, and, considering the importance of the area involved, they give rise to comparatively slight inconvenience, but ruptures of the distal tendon at the elbow were hitherto practically unknown. Mr. Platt describes the symptoms and successful treatment of a case, which he is probably right in supposing to be unique in surgical literature. The bicipital fascia and the attachment of the tendon to the radius had wholly disappeared at the time of operation, but complete recovery of function followed reattachment of the tendon through a tunnel fashioned in the bone.

Rupture of the ligamentum patellae, and tears of the insertion of the rectus femoris, are also described in Mr. Platt's paper, which contains much sound advice, the outcome of a rich experience and good judgement.

AN ADVANCE IN EXCRETION UROGRAPHY

The uncertainty of some of the earlier methods in excretion urography has made instrumental pyelography the method of election with genito-urinary surgeons. Professor A. von Lichtenberg of Berlin, who was a pioneer of the instrumental technique, has recently achieved results with certain new contrast substances by which the excretory method acquires a fresh importance as a supplement to instrumental urography, and in some cases must supplant it. As will be seen from the report of the proceedings at the Royal Society of Medicine, printed at page 625 this week, he claims that the new preparations have decided advantages over uroselectan and abrodil, which have been in use until now. Not the least is the fact that their toxicity is much lower ; uroselectan B, to which Professor von Lichtenberg has given the name D. 40, can be given in a dose of 20 c.cm., and produces no untoward effects. The iodine content of the new substances is only between one-fifth and three-fifths of the amount previously thought to be necessary ; their elimination, moreover, occurs much more rapidly, D. 40 appearing in the urine in its highest concentration about fifteen minutes after injection ; this is a decided advance, the excretion of the older substances having been delayed for an hour to an hour and a half after injection. The rapidity with which a high proportion of the preparation is eliminated gives an index of kidney function which cannot be obtained by the instrumental method. A negative result with the excretion method has therefore a certain value, indicating that the concentration power of the kidney is too severely damaged for secretion to take place. Various advantages of an excretory over a mechanical method of urography can be readily appreciated, such as the avoidance of distension of the pelvis with injected fluid and its consequent distortion or irritation, and the discovery of fixations or deformities of the ureter, which cannot be readily detected with a ureteric catheter in place. Such admitted advantages have only been awaiting the perfection of an excretory technique. Professor von Lichtenberg has found that other details come to light

with the use of the new method. For example, the instrumental method may induce an irritation of the pelvis, which prevents the filling of one or more calyces, and so gives rise to a faulty impression of the state of the kidney. The absence of irritation by the excretory method leads to a uniform filling, often finer in detail than that produced by the injection of fluid from below. Again, the excretory method may show that obstruction by a stone impacted in the ureter is only partial, although preventing the passage of a catheter. He believes that the new contrast substances mark an advance in technique which will be reflected in improvement of diagnosis, and hence of treatment in kidney conditions. The compliment he has paid to the Section of Urology by coming to England to announce the results of his work on this subject was duly appreciated at the meeting held on March 26th.

THE NATIONAL HEALTH INSURANCE SERVICE

In the *Canadian Public Health Journal* for February last appears an article, entitled "National Health Insurance Medical Service in Great Britain," which contains probably the best descriptive account of that service which has yet been published within similar compass. It is from the pen of Mr. R. W. Harris, whose book on *Medical Insurance Practice* should be a familiar possession of every insurance practitioner in this country. The article may be commended to the attention of all those who would like to know broadly what the service really is, but who have time to read only a few pages on this subject. Mr. Harris's article is singularly complete in its descriptive survey, every essential feature and characteristic of the service being lucidly set out. There is perhaps only one fact the omission of which is to be regretted. It seems desirable, when describing the service to those who are ignorant of it, that whenever the statement is made that an insurance practitioner, single-handed, may accept on his list persons up to a maximum number of 2,500, there should be added the even more important statement that the average number of insured persons on a practitioner's list is actually in the neighbourhood of 900 only. Mr. Harris notes as perhaps the two most essential and remarkable features of the service, its retention of all the best characteristics of private practice, and the extent of the share accorded to the medical profession itself in its administration. "Comparing the English system with all the other Continental systems," he says, "the difference is very marked, and that is doubtless the reason why, compared with the Continental system, the doctors here are comparatively satisfied, and in my opinion give a better service." He adds—and this is important in view of certain recent utterances of one or two members of the profession of some eminence—"Criticism of the service from those medical men not engaged in it is now confined to very few and occasional critics whose observations, often ill informed and twisted out of any real resemblance to the facts as they are, make it difficult to treat them seriously." Mr. Harris's article contains two paragraphs which might have been better omitted, in view of the general scope of the article and the limited amount of space at his disposal; indeed, the author himself says of one of them, "I realize that such scrappy comments seem hardly worth while." The tentative proposals for considering the extension of the service to the dependants of insured persons and others are, of course, based, not upon the value of the health of these dependants to employers of labour, but upon the supposition that in the not distant future the community as a whole may regard the health of its individual members as a national asset to be nationally catered for. With regard to an alternative salaried medical service, no one questions either the amenities or the good work of the Civil Service, but were the conditions of such a service applied to medical practice it would be very difficult, if not impossible, to preserve the two great features mentioned above as being commended by Mr. Harris, and there would be other manifest disadvantages. The concluding paragraph of the article, concerning the relationship of the insurance service to preventive medicine, is important. While noting that the service is preventive in the sense that the doctor is consulted in earlier stages of illness than would otherwise be the case, the author goes on to say: "In the wider sense real preventive effort became largely unattainable when it was decided to create *ad hoc* bodies for administration. This will some day be remedied, and the insurance committees will become merged in new committees of the county and county borough councils."

EPIDEMIOLOGY OF ACUTE POLIOMYELITIS

The recent incidence of acute poliomyelitis is discussed by Dr. Pierre Sée in the issue of the *Gazette des Hôpitaux* for February 14th, which is devoted to a consideration of this disease. In 1926 the countries chiefly affected were Scandinavia, England, Germany, Hungary, and France, where about twenty cases occurred, scattered over Savoy, Pas-de-Calais, Loiret, La Vendée, and Aube. During the next two years there was a general decline of the disease, but in 1929 fresh outbreaks occurred in Switzerland, North Italy, Holland, and Belgium, as well as isolated cases in La Vendée, Haute Saône, Calvados, Aube, Savoy, Jura, and the Landes in France. In 1930 numerous cases were notified throughout France and particularly in the Lower Rhine and Moselle district, where the epidemiological and experimental aspects of the outbreak were studied by Levaditi, Schmutz, and Villemin. The epidemic in the Lower Rhine district lasted from July to October, and gave rise to 405 cases, or a proportion of 60.3 per 100,000 inhabitants. Of these cases, 110 occurred at Strasbourg, 61 in the canton of Schiltigheim, and 53 in the canton of Bischwiller. Four-fifths of the patients were children under 5 years of age. Levaditi and his collaborators found experimentally that the virus of this outbreak had a relatively attenuated virulence, which accounts for the maximum incidence at that time of life. The epidemic in the Vosges coincided with outbreaks in Belgium and Northern France, as well as with a recrudescence of the disease in Sweden, Denmark, and Spain. In Germany the frequency of the disease was about the same in 1930 as in the previous year, the case mortality during the period 1927 to 1930 showing a progressive decline from 15 per cent. in 1927 to 9.5 in 1930. In Switzerland the disease tends to be stationary, with 200 cases a year, the incidence being higher in the rural districts than in the towns. An

epidemic also occurred in Finland in 1930. Outside Europe the disease has recently been more frequent among children in various parts of Madagascar. In the United States 594 cases had been notified by October, with the following distribution: Ohio, 109 cases; New York, 65 cases; and numerous others in Kansas, California, and Connecticut, as well as isolated cases in various other States. The spring and summer were the seasons of predilection.

IN DARKEST LIBERIA

In 1787 Great Britain acquired Sierra Leone for the purpose of providing liberated slaves with a homeland in Africa. In 1816 the American Colonization Society was formed for the purpose of devoting itself to the welfare of a similar class in the United States; and five years later the foundations of the present Republic of Liberia were laid. The affairs of this republic have received much unfavourable attention in recent weeks on account of alleged slavery—a curious situation in a republic of this nature. Very little, however, is known about Liberia. Whereas Sierra Leone is now a well-organized country about which we possess a considerable fund of information, Liberia has remained for many years the least known of all the African countries—the darkest spot in darkest Africa. Recently Professor Strong of Harvard University Medical School, with a number of his colleagues, made an extensive biological and medical survey of the country, penetrating a considerable distance into the hinterland as well as surveying the better-known coastal lands. The expedition then crossed Central Africa, through the Belgian Congo to Nairobi. The results of that expedition have recently been issued as two handsome volumes[1] by the Harvard University Press, and provide a most illuminating account of the conditions which prevail there. Liberia now has a population of about one and a half to two million inhabitants, of whom between ten and twenty thousand are descended from the "repatriated" negroes, and are called Americo-Liberians; the remainder are indigenous Africans. The Americo-Liberians live on the coast, and the government of the country is entirely in their hands. The inhabitants of the hinterland are not represented in the Liberian Assembly, though they pay taxes and are liable to forced labour, which is apparently not far removed from a form of slavery. The capital of the country is Monrovia, a town without a general water supply or sewage system. It has, however, a large swamp where mosquitos breed. Fortunately, most of the inhabitants appear to be more or less immune to the effects of malaria, which, as might be supposed, is still very common. The history of Liberia in respect to hygiene and sanitation has been, in general, very simple; and the present situation is even simpler. There is no health organization of any sort, no adequately trained sanitarian or physician, no public health laboratory. There is a Government hospital of sorts, but it is in charge of a poorly trained Liberian physician and a Liberian nurse—the only gesture the country has made towards the care of the sick. Drinking wells and latrines share the same porous soil of the back yards of Monrovia. There are, of course, no public health statistics and no records of births, marriages, and deaths. Until recently there have been two or three private European physicians in the country; but several more are now at work in connexion with the establishment of the Firestone Rubber Plantations. The Harvard expedition has collected much valuable information about the sanitation and diseases of the country. The chief of these include malaria, helminth infections of various kinds, yaws, leprosy, syphilis, gonorrhoea, tuberculosis, small-pox, chicken-pox, and various skin conditions. More rarely one encounters pneumonia, bacillary dysentery, typhoid, trypanosomiasis, yellow fever, beri-beri, and nutritional diseases, while plague and relapsing fever are absent. Some of these are considered in detail in the report, more particularly malaria, yellow fever, schistosomiasis, leprosy, filariasis, onchocerciasis, yaws and syphilis, leprosy, skin diseases, and trypanosomiasis. Important as is the contribution to the medical problems of the country, the report is by no means limited to their consideration. It embraces a most interesting anthropological account of the peoples, a detailed investigation into the flora and fauna of the country, and briefer accounts of the geology, geography, and history. It is extremely well illustrated, both with half-tone plates and with coloured drawings. It shows that, potentially an extremely wealthy land, Liberia is very backward in the services essential for the proper development of a tropical country. The recent establishment of the Firestone Plantations should have an immense influence on the expansion of health services, as well as on the reduction of the admittedly undesirable practices of some of its inhabitants. "Big Business," in the Tropics cannot afford merely to look for profits; it must see that proper conditions are not only established but maintained; and the Firestone corporation is well aware of this necessity.

A MEDICAL LORD CHESTERFIELD

During the last year of the war Dr. Clément Simon, then in charge of a military hospital devoted to the treatment of skin affections and venereal disease, was allotted as a colleague a young practitioner, who, though well versed in general medicine, knew singularly little of dermatology or venereology. Being, however, endowed with intelligence and aptitude, he soon, under the guidance and tuition of his chief, became a colleague both skilled and trustworthy. Separated from his teacher by the exigencies of the peace, which seemed likely to bring his dermatological studies to an untimely end, he exacted a promise from Dr. Simon to continue the instruction by correspondence. The pledge so given has been amply redeemed, and the epistles of the professor, carefully preserved by the disciple, have now, to adopt a more modern metaphor, been "released" for the benefit of the general medical public. The letters[1] are forty-six in number, and, no doubt with the object of preserving the epistolary flavour, they are all printed in italics. The resulting volume is not

[1] *Lettres à un Médecin Praticien sur la Dermatologie et la Vénéréologie.* Par Clement Simon. Paris: Masson et Cie. 1930. (35 fr.)

in any way a textbook, but it comprises an interesting series of observations and speculations on subjects and topics occurring in the everyday practice of a learned and skilful physician. All kinds of interesting points are discussed, and the letters (or chapters) vary greatly in length. Syphilis is the foundation of about a third of the whole series. One of the subjects discussed at some length is syphilis and marriage. This question was studied and reported upon by a strong committee of the French Society for the Study of Dermatology and Syphiligraphy in 1920, and the author is of opinion that nothing has occurred since then to modify the conclusions arrived at. Shortly, his opinion is that a patient whose treatment has been started during the "pre-serological" period may marry after a year's treatment and a year's observation; if treated after the development of a positive serum reaction, but before the appearance of secondary signs, he must wait four years; if he presents a persistently positive Wassermann reaction he may marry provided the cerebro-spinal fluid is normal; but if the patient is a woman she must have a course of treatment during every pregnancy. Interesting topics of less gravity also discussed by Dr. Simon are eruptions due to the use of eau-de-Cologne, lupus erythematosus and its treatment by gold preparations, and pediculosis in ladies of the higher social strata. The occasional incidence of this humiliating infection he ascribes to the fact that clothing which conforms to the dictates of modern fashion affords insufficient protection against the contact of the skin with the seats of public conveyances. It is to be hoped that the anonymous recipient of these letters will do his mentor more credit than the son to whom the fourth Earl of Chesterfield addressed his celebrated series.

PROGRESS OF CREMATION

At the annual meeting of the Cremation Society, held on March 25th, the chairman of council, Mr. Murray N. Phelps, stated that during 1930, at the twenty crematoriums in Great Britain, 4,527 cremations were carried out, comparing with 4,341 in 1929. The municipal crematoriums now number ten; the other ten are owned by proprietary companies or cemeteries. Since the first crematorium was opened, at Woking, in 1885, a total of 52,921 cremations have been carried out in this country. The latest figures from Germany afford a striking contrast to the British figures, as the number of crematoriums in that country has reached a total of 103, and the annual number of cremations now exceeds 50,000, almost equalling in one year the British achievement for the last forty-five years. An account of the jubilee of the Danish Cremation Society, which was given to the meeting, showed that in Denmark, also, cremation is making rapid progress; the membership of the society is 63,000, and Denmark has five crematoriums, with four more in contemplation. Mr. Murray Phelps said that owing to the increased interest in cremation shown by the working classes in this country, efforts have been made to include cremation at a nominal charge under health insurance benefits. The municipal and proprietary cremation authorities have unanimously agreed to make a reduction of the fees in such cases, but so far it has not been possible to get this question considered by the Ministry of Health.

NARCOTIC DRUGS IN EGYPT

In the *Journal* for February 1st, 1930 (p. 208), attention was called to the exposures by Major-General T. W. Russell Pasha of a mid-European source of illicit production and distribution of narcotic drugs. Tons of heroin, morphine, and cocaine were reported to have passed through Genoa, Trieste, Piræus, and Constantinople into Egypt, which country was said to contain some 500,000 addicts to these drugs. Russell Pasha as director of the Central Narcotics Intelligence Bureau of the Egyptian Government, has just issued his report for the year 1930, in which he relates the rigorous action he has continued to take against foreign smugglers of the above-named alkaloids, opium, and hashish into Egypt. He produces photographs of the most notorious traffickers who have been deported from Egyptian territory, and describes the means by which several organized gangs of drug smugglers have been traced, exposed, and convicted. The report contains also illustrations showing the misplaced ingenuity employed in concealing the contraband drugs. Weighing-machines with false floor-boards, hollowed out water-closet seats, millstones stuffed with bags and tins of hashish, and blocks of wax enclosing tins of heroin afford samples of the resources employed to evade the vigilance of the customs authorities. As might have been anticipated, the newly established drug factories in Stamboul, to which attention was called in our issue of January 31st last (p. 190), have provided a fertile source of the illicit imports into Egypt. Four tons of heroin were admittedly consigned from these factories in six months, or about double the estimated annual requirement of the world for medical and legitimate purposes. This alkaloid appears to be that most largely resorted to by Egyptian addicts, though tons of hashish have been seized by the police and customs authorities. The narcotic laws now in operation in Egypt are certainly stringent, and their administration in the hands of Russell Pasha is commendably drastic; moreover, the cultivation of opium, which has been carried on for years, is now absolutely forbidden. The conference on limitation of narcotic drugs, which assembles at Geneva next month, will have something to learn from the vigorous methods that have been adopted in the land of the Pharaohs.

We regret to record the death, on April 1st, at the great age of 92, of Professor William Carmichael M'Intosh, M.D., F.R.S., who held for thirty-five years the chair of natural history in the University of St. Andrews.

THE KING

The attack of subacute bronchitis from which the King has been suffering since the close of last week has naturally given rise to concern in the public mind; and medical men who are asked to interpret the reassuring statement that "His Majesty is making slow but satisfactory progress" will do well to underline the word "slow," because a bronchitis which has probably involved the tubes within the lung and has occurred at the end of the winter must take time for recovery.

NINETY-NINTH ANNUAL MEETING
of the

British Medical Association

EASTBOURNE, 1931

BEACHY HEAD

THE ninety-ninth Annual Meeting of the British Medical Association will be held at Eastbourne this summer under the presidency of Dr. W. G. Willoughby, medical officer of health for Eastbourne, who will deliver his address to the Association on the afternoon of Tuesday, July 21st. The sectional meetings for scientific and clinical work will be held, as usual, on the three following days, the morning sessions being given up to discussions and the reading of papers, and the afternoons to demonstrations. The Annual Representative Meeting, for the transaction of medico-political business, will begin on the previous Friday, July 17th. The provisional programme for the work of the fourteen Scientific Sections is being drawn up by an Arrangements Committee, consisting partly of Eastbourne representatives and partly of members appointed by the Council of the Association. The full list of presidents, vice-presidents, and honorary secretaries of the Sections, together with the provisional time-table, was published in the *Supplement* of March 7th. Other details of the arrangements for the Annual Meeting will appear in later issues. During the week, and in particular on the last day of the meeting (Saturday, July 25th), there will be excursions to neighbouring places of interest. We publish below, the second of a series of articles on Eastbourne and its neighbourhood, with special reference to medical institutions. The first article—"Eastbourne in History and To-day"—appeared in our issue of March 14th (p. 464).

THE HOSPITALS OF EASTBOURNE

Owing to the rapid growth of the borough of Eastbourne, the general hospital and similar institutions, though efficient for their purpose, are not as attractive architecturally as they might have been had allowance been made in their original plan for a series of additions to meet urgent requirements. The beautiful buildings of All Saints Convalescent Hospital might be mentioned as an exception.

The general hospitals include the Princess Alice Memorial Hospital, the Leaf Homoeopathic Cottage Hospital, and St. Mary's Hospital (formerly the Poor Law Infirmary).

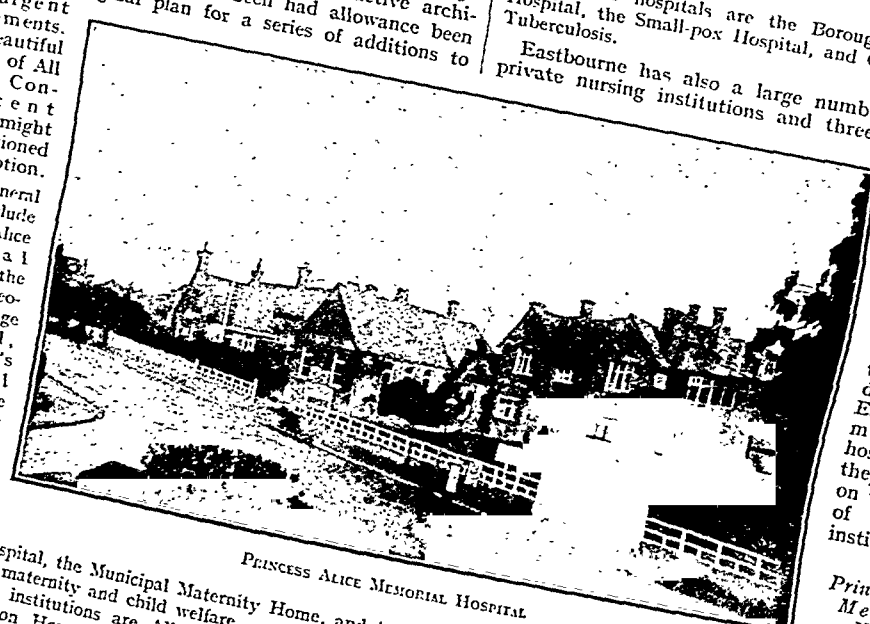
The special hospitals are the Royal Eye Hospital, the Municipal Maternity Home, and the Bell Hostel for maternity and child welfare.

The convalescent institutions are All Saints Convalescent Hospital, the London Homoeopathic Hospital Convalescent Home, and the Sailors and Soldiers Convalescent Home.

The fever hospitals are the Borough Infectious Diseases Hospital, the Small-pox Hospital, and Gildredge Hospital for Tuberculosis.

Eastbourne has also a large number of well-equipped private nursing institutions and three municipal clinics.

There is a thriving branch of the Royal Surgical Aid Society, and a very efficient division of the St. John Ambulance Brigade. During the war the V.A.D. detachments of Eastbourne had many local hospitals, and they still carry on work at two of the above institutions.



PRINCESS ALICE MEMORIAL HOSPITAL

Princess Alice Memorial Hospital

The general hospital for Eastbourne and the surrounding parts of Sussex was named after H.R.H. Princess Alice, sister of King Edward VII. It was opened in June, 1883, by the Prince and Princess of Wales, afterwards King Edward VII and Queen Alexandra, the foundation stone having been laid in the previous July by

His Majesty's sister, H.R.H. Princess Christian. The hospital has had to be continuously extended in order to meet the growing requirements of the district. It began with two wards of 10 beds, and has been enlarged from time to time; when the additional buildings now under construction have been completed it will provide accommodation for 110 patients, and be capable of treating about 1,800 in-patients annually. The radiological, electrical, massage, therapeutical, and pathological departments and laboratories, which have been added by degrees, will be brought thoroughly up to date in the buildings now in course of erection.

The hospital at present accommodates 96 in-patients. The staff consists of two resident medical officers, a matron, house and sister tutor, eight sisters, ten staff nurses, twenty-one nurses, twenty domestics, besides porters, etc. The chief work of the hospital is the care and treatment of in-patients. An increasing number of these, however, continue to be treated after they have left the hospital, mainly in radiological, electrical massage, and massage departments.

The management includes a number of prominent residents of the town and surrounding country, from whom are chosen a house committee, finance committee, and enlargement and improvements committee. There is also a strong and influential medical committee. The services of the physicians and surgeons are gratuitous.

The Leaf Homoeopathic Cottage Hospital

The foundation in 1888 of this cottage hospital of 16 beds was due to the beneficence of two ladies, the Misses Leaf, who placed in the hands of trustees the two properties Nos. 1 and 2, Marine Road. Later No. 3, Marine Road was added through the generosity of Mr. Alfred Tabor, as a memorial to his son. Since the hospital was established over 12,000 patients have received treatment. Although it has been brought up to modern requirements, it is still inadequate for the increasing demands made upon it, and removal to an up-to-date building has become an urgent necessity. It is the desire of the committee to erect a model cottage hospital of 25 beds on a site which has recently been acquired.

The honorary medical staff consists of three local practitioners. The services of three consultants are also available. The nursing staff comprises a matron, sister, and four nurses. The average stay of in-patients is three weeks; many of these attend later as out-patients.

St. Mary's Hospital

This hospital was the Poor Law Infirmary of the Eastbourne Union until April, 1930, when it was transferred to the borough council. The original building, which dates from 1889, had 120 beds. By alterations and late guardians were able to hand over to the council a satisfactory and efficient hospital. The new buildings included a separate maternity block and nurses' home, as well as up-to-date wards. Owing to its situation and dependence for certain services on the institution in the same grounds, the hospital is not separated in management from the Public Assistance Committee.

The number of beds is as follows: for men 50, women 82, maternity cases 7, children 20, and for the generally infirm 26, making a total of 185. An extension of 16 beds is being arranged. With the exception of 12 beds, which are retained for county cases, the hospital serves Eastbourne only. The treatment of out-patients is confined to emergencies and after-treatment. There is a special department for massage, light, and electrical treatment. The medical superintendent (non-resident) has the assistance of a consulting surgeon and other specialists as required. There is no resident house-surgeon. The hospital is a training school for probationer nurses.

The ... Nose, and Throat Hospital

This hospital, ... Cavendish Place, founded in 1917 by Dr. M. V. Mc... hnie, Dr. Ashley Cluffe, and Councillor W. E. Wo... commenced as a small room for out-patients only. In 1921 the committee purchased No. 49, Cavendish Place, and provided accommodation in three wards for twelve in-patients, and for out-patients. The adjoining house, No. 47, was purchased, reconstructed, and equipped, and was opened in December, 1930. There are now six wards with 17 beds, and accommodation for out-patients has been greatly improved. The operating theatre and anaesthetizing room are on the first floor, where the wards for men, women, and children are also situated. In 1930 there were 308 in-patients and 1,942 out-patients. The recent extension will enable a much larger number of both classes of patients to receive treatment.

The Royal Eye Hospital

This hospital was founded in 1914 by the late Dr. Ewart and Dr. Milner Moore. The accommodation, to begin with, was only two rooms, where out-patients were attended. Largely through the efforts of the late Alderman C. F. Simmons, the present premises in Cavendish Place and Pevensey Road were acquired, and the hospital is now fully equipped to deal with all sorts of ophthalmic diseases.

The accommodation consists of 14 beds and an operating theatre. On an average about 100 out-patients are treated weekly, and during a year about 150 operations are performed. The nursing staff comprises a matron and four assistant nurses. The hospital is entirely supported by voluntary subscriptions and donations, and is governed by a board of management under the chairmanship of Councillor E. H. Hill.

Municipal Maternity Home

This popular home was opened in March, 1920, in a private house with a large garden. Extensions were completed in May, 1925. The 16 maternity beds are increasingly used. In 1930, 248 cases were admitted; this number represented over 35 per cent. of the total births in the borough. There is a consultant obstetric surgeon, but the mothers are attended by their own doctors or by the resident midwives. In connexion with the training school for midwives. The home is a home there is an ante-natal and post-natal centre, where medical practitioners can attend their patients if they wish. As no patients are admitted or attended by the external midwife without ante-natal consultation, this advantage is assured in at least 50 per cent. of births in the borough, independent of ante-natal consultations elsewhere.

The Bell Hostel

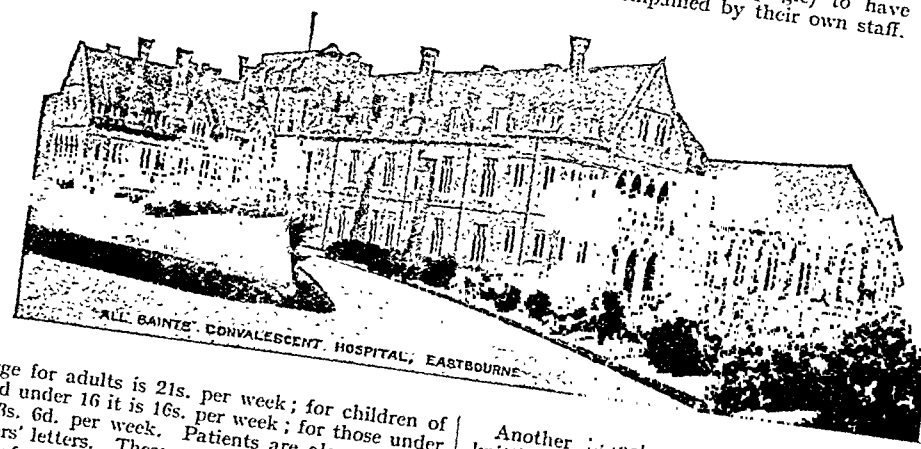
The Bell Hostel, in Salehurst Road, is a Church of England maternity home for unmarried mothers, and a boarding-out home for their children.

All Saints Convalescent Hospital

The All Saints Convalescent Hospital is situated at the foot of Beachy Head, and consists of two buildings—one for adults, with about 70 beds for men and 120 beds for women patients, the other for children, with beds for over 100 children of ages ranging from 3 to 16 years. In the Children's Hospital there are also 5 beds for mothers with infants under 6 months. The present building for adults was opened in 1869 on a site given by the Duke of Devonshire. The Children's Hospital was opened considerably later, in 1890. Both hospitals and the grounds surrounding them are the property of the All Saints Community.

The hospital is under the care of four visiting physicians. For each of the three departments—men, women, and children—there is an experienced trained nurse, responsible for the medical care of her patients under the supervision of the visiting medical officers. Patients are admitted on a medical certificate filled in by their own doctors and approved by the hospital medical officers. The adult hospital is approved by the Ministry of Health for the admission of ambulant non-pulmonary cases of tuberculosis. Persons over 70 years and those convalescent from infectious or contagious

diseases are ineligible. Patients are expected to be up and about during the day, and able to manage generally for themselves. Bed cases are ineligible. The usual length of stay is three weeks, but this period can be extended with the approval of the hospital medical officers. Patients are sent for convalescence by the chief hospitals in London and the provinces, and by health insurance and other charitable societies. Over 3,000 patients are admitted in the course of the year. The hospital is open all the year round, and to patients of all religious denominations. Children have to obtain a negative result of nasal-throat swab before admission.



The charge for adults is 21s. per week; for children of 12 years and under 16 it is 16s. per week; for those under 12 years, 13s. 6d. per week. Patients are also admitted on subscribers' letters. These are issued to regular annual subscribers of 21s. or more, one letter for each 21s. subscribed. There is an additional charge of 25s. 6d. for three weeks on these letters.

The sister superior, who is responsible for the management of the hospital, realizes fully the importance in convalescence of fresh air, rest, and plentiful nourishing food. Application for admission and all inquiries about the hospital should be addressed to the secretary. The hospital is open to visitors every afternoon except Sunday, and the sisters always welcome visits from those who are interested in the work.

The London Homoeopathic Hospital Convalescent Home

With promised liberal support, it was decided in 1887 to establish the above home for the reception of convalescent women and girls, and the home was opened in August of the following year. It has proved a valuable help to the hospital by enabling patients to be discharged from the wards at an earlier date than would otherwise be possible. Since its foundation the home has received an average of 200 patients annually, a large number having undergone severe operations. It has also provided a very useful service in accommodating hospital nurses during short periods of rest.

In 1888 the home was started as a separate institution, but it has now become incorporated with the London Homoeopathic Hospital under a Royal Charter granted in 1928. A subscriber of £3 3s. per annum is entitled to recommend an eligible patient for residence at the home for three weeks.

Sailors and Soldiers Convalescent Home

This home is organized and staffed by V.A.D. Sussex 2, assisted by a trained nurse. There are 53 beds for Ministry of Pensions cases; 2,773 patients have been admitted since the detachment (commandant, Mrs. F. S. Williams) undertook the management of the home in 1919, when it was recognized by the Ministry of Pensions. Ex-service men, the majority being surgical cases, are sent by the Ministry for convalescent treatment. They come from all parts of England and Wales, and occasionally from Scotland. Since the number of ex-service men eligible for treatment under the Ministry of Pensions has decreased, the home has been able to admit patients recommended by the Emergency Help Committee of the Joint Council of the Order of St. John of Jerusalem and the British Red Cross Society—men severely disabled, who would otherwise not be able to get treatment in a convalescent home, or who are too helpless to go to the seaside for a holiday. Each summer Mrs. Hay of Gifford House, Roehampton, arranges for about forty-eight patients (mainly paraplegic) to have a seaside holiday here, accompanied by their own staff.

Another branch of the home is concerned with the knitting industry, which was started in 1921 to employ severely disabled ex-service men trained under the Ministry of Labour. Their number has risen from four to fifteen, twelve being employed in the workshop and three in their own homes. Proceeds from sales have increased from £992 in 1923 to £3,378 in 1930, but it is most difficult to keep these men employed all the year round, and appeal must be made to the public to support them by buying their work.

Borough Infectious Diseases Hospital

The general isolation hospital is situated in East Dean Road at the foot of the Downs, and has 62 beds in seven blocks. The number of separate wards enables various diseases and observation cases to be admitted, apart from scarlet fever and diphtheria. An unusual provision in a health resort, but a long-established feature, is that the private schools have their own blocks in the grounds, so that they have not to maintain separate sanatoriums. The medical service at these blocks is provided by the hospital staff. The hospital has been added to from time to time, the latest blocks being erected in 1904.

Small-pox Hospital

This hospital of 18 beds in three wards is situated on the Crumbles near the sea, and just outside the borough in the parish of Westham. The surrounding rural districts have contracted for the use of the hospital, but it is entirely under the management of the Eastbourne Borough Council.

Gildredge Hospital

This hospital is situated near the Infectious Diseases Hospital at the foot of the Downs, and is solely for the treatment of pulmonary tuberculosis. There are 24 beds in bungalows of 2 beds each—12 for men and 12 for women. The hospital was opened by Sir Arthur Newsholme, the Chief Medical Officer of the Local Government Board, in 1914. It is a hospital for tuberculosis, and not a sanatorium, being used mainly for advanced cases and for the institutional accommodation of patients awaiting admission to sanatoriums. It has been one of the most useful institutions of the borough, enabling a very large number of patients to receive institutional treatment. The clinical medical officer is a practitioner in the borough.

MATERNITY WORK IN HONG-KONG

WITH SPECIAL REFERENCE TO TROPICAL DISEASES ASSOCIATED WITH PREGNANCY

BY

ANNIE SYDENHAM, M.R.C.S., L.R.C.P.

The Alice Memorial Maternity Hospital, part of the Alice Memorial and Affiliated Hospitals, Hong-Kong, provides accommodation for fifteen patients; in addition, beds are available in the adjacent Women's Hospital for the ante-natal treatment of patients with concurrent medical complications; there is also an isolation ward for septic cases.

During the period under review—1926–30—there were 1,600 deliveries, about one-third of the patients being primiparae. Most of the women were seen for the first time on their admission to hospital, often after the onset of labour, though the attendances at the ante-natal clinic gradually increased year by year. As the patients were all Chinese, opportunity was afforded for comparing their pelvic measurements with those of English women. It was found that on the whole the measurements of the Chinese (mostly Cantonese) were smaller; there were many cases of natural delivery or easy forceps delivery in patients with an external conjugate diameter of between 6½ and 7 inches, and with correspondingly small interspinous and intercristal diameters. The babies, however, were usually smaller, the average weight being nearer 6½ than 7 lb. The most difficult forceps cases were those in which the pelvis was normal, with a large and unyielding foetal head, often due to post-maturity. There were very few cases of serious pelvic contraction, and the only case where Caesarean section was performed in this series of 1,600 cases was in a very small, deformed, kyphotic woman. Very few people in Hong-Kong suffer from rickets, and osteomalacia is unknown there.

Abnormal Labour

Presentations other than vertex were as follows: breech 44, face 4, brow 1, transverse 7, and twins 22. The large number of breech deliveries is accounted for partly by the fact that external version was seldom performed, and partly by the fact that several of these breech deliveries were of premature (often syphilitic) foetuses. With regard to twin deliveries, it is interesting to note that three out of the twenty-two patients suffered from severe toxaemia of pregnancy, one of them dying from eclampsia and one from yellow atrophy of the liver; the third recovered from pregnancy toxaemia with acute nephritis.

Forceps were used in 77 cases (4.8 per cent.), and craniotomy was performed twice, one of the two patients being an eclamptic, who subsequently had a living child after a normal labour.

Drugs during Labour

Potassium bromide and chloral were the chief analgesics used, but in primiparae having severe pain 1/4 grain of morphine was sometimes given before the first stage was too far advanced; no ill effects were noted in the foetus in any of these cases. During the second stage use was made increasingly of 1/2 c.cm. of pituitrin in cases where delay occurred after the head was on the perineum. These cases had previously formed the bulk of our forceps deliveries; by the administration of pituitrin the number of forceps cases was reduced by one-half during 1929. Where instrumental delivery ultimately became necessary, there was a perceptible strengthening of uterine contractions, with consequent prevention of post-partum haemorrhage.

Complications during Pregnancy and Labour

Complications during pregnancy and labour were as follows:

Pre-eclamptic symptoms	16
Placenta praevia	15
Accidental haemorrhage	11
Beri-beri	10
Eclampsia	9
Ankylostomiasis	6
Prolapsed cord	5
Hydatidiform mole	4
Hyperemesis gravidarum	3
Acute yellow atrophy of liver	2
Hydramnios (severe)	1

There were many other medical complications not enumerated above, such as valvular disease of the heart, myocarditis with chronic bronchitis, pneumonia, broncho-pneumonia with empyema, acute phthisis, acute and chronic nephritis, pyelitis, cystitis, venereal diseases, amoebic hepatitis and amoebic dysentery, malaria, etc. It will be seen from the causes of death given below that these complications were responsible for nearly half the deaths recorded.

The case of hydramnios was of special interest, as the foetus was an anencephalic monster presenting by the face, and accompanied by 150 oz. of liquor amnii. Although the mother was only 24 years old, this was her sixth pregnancy. The previous children were all living and healthy, but the husband had recently died of syphilis.

The figures referring to eclampsia are too small to furnish any deductions, but the after-history of three of the cases is noteworthy. All three patients had severe eclampsia with marked oedema and albuminuria in their first pregnancy. It is probable that albuminuria had continued for some time, as none of these patients came under observation before labour. It would therefore seem more reasonable to expect permanent kidney damage in these cases than in most of the cases in England which come under observation early and receive prompt treatment. The urine, however, was free from any trace of albumin during their second pregnancy, and no symptoms of toxaemia were present. The labour and the puerperium were normal in the three patients, each of whom had a living child.

The study of beri-beri in pregnant women is of special interest in view of the statement that this disease occurs almost solely in males.[1] I have not seen any cases in non-pregnant women, though I have heard of their occurrence, but it is certain that pregnancy predisposes to the disease, probably on account of the extra demand which it makes on metabolism. Besides the ten cases enumerated above, several others have come under observation during the puerperium, the patients having been admitted into hospital after delivery in their own homes. Features common to most of the cases were oedema, varying in severity; enlargement and incompetence of the right heart; and albuminuria (usually slight). In the three fatal cases oedema was extensive, and the "swelling" of the heart correspondingly severe. Moreover, these patients had no period of rest in bed before labour, and in all three cases operative delivery was necessary. In regard to the central nervous system, the special features in most cases were numbness and loss of power, sometimes in the legs only, but sometimes also in the arms. There was usually tenderness on pressure of the calf muscles; a few of the patients complained of very severe pains in the limbs during the first two or three weeks of the disease. Wasting of the calf muscles was apparent during the puerperium, after subsidence of oedema, and peroneal atrophy with foot-drop became marked in some patients.

[1] Cannon, Alexander: Some Observations on Beri-beri, *British Medical Journal*, 1929, ii, 852.

As to the effect of beri-beri on labour, four of the ten patients required forceps delivery, one because of face presentation, two on account of the serious condition of the heart, and one owing to weakness of labour pains. Poor uterine contractions were noted in some of the cases. Four of the babies were stillborn, or died within the first two days. As the blood pressure is low in this condition, and as heart stimulants are required during labour, pituitrin is particularly useful in these cases, having the double effect of stimulating the heart and strengthening uterine contractions.

However great a part vitamin B deficiency may play in the causation of this disease, the effect of dietetic treatment alone was found of little value when once the symptoms were well marked. Two patients who had suffered from the disease in a previous pregnancy came for treatment at the onset of early symptoms of numbness, and in these cases dietetic treatment proved sufficient to arrest the disease.

Treatment during the puerperium is difficult in most Chinese patients. As soon as the heart condition clears and the pains in the limbs disappear, with improvement in the general condition, they seldom have patience to wait until they regain the use of their limbs. The few who remain for a prolonged period are greatly benefited by massage treatment after the painful stage. Without treatment it is sometimes as long as six months before a patient recovers the complete use of her limbs.

Ankylostomiasis becomes a serious disease in pregnant women. The greater demand made on the blood by the growing foetus soon reveals the incipient anaemia, and the picture is a typical one. The face is pale, the lips and conjunctivae almost white; there is a general oedema, with shortness of breath, and often a hard, unproductive cough. Examination often discloses a systolic heart murmur, crepitations at the bases of the lungs, and a cloud of albumin in the urine. Microscopical examination of the faeces in these cases reveals the presence of ankylostoma eggs in sufficient numbers to suggest a heavy infection. Treatment consisted in the giving of 3 c.cm. of carbon tetrachloride, followed by iron and arsenic injections. If eggs were still present after two weeks the treatment was repeated. The babies were very small for the period of pregnancy, and in only two of the cases did the baby survive for more than a few hours. In every case, however, the condition of the mother showed marked and rapid improvement after treatment. In one case of repeated miscarriages I found and treated ankylostomiasis, and the patient subsequently had a living child.

Complications during the Puerperium

Of the deaths recorded during the four years under review, there was only one from puerperal sepsis. The case of secondary post-partum haemorrhage—the patient died on the twelfth day—might also be included under this heading, as a retained succenturiate placenta was found to be the cause of haemorrhage. The percentage of deaths from puerperal sepsis was 0.13.

It is surprising how seldom a case of severe puerperal sepsis is seen, though mild cases of sapraemia are not rare. In these cases the injection of glycerin into the uterus, together with daily mixed phylacogen injections, soon bring the fever down and clear up the condition. It is difficult to explain why we get so few cases of severe sepsis, except on the theory that the patients have acquired a strong resistance to streptococci on account of previous chronic infections. We find that better-class patients, who have lived more sheltered lives, are less resistant to infection. The causes of auto-infection, such as septic teeth, constipation, and gonorrhoea, are probably more prevalent in Hong-Kong than in England.

Mortality

The causes of death during the period under review were as follows:

Eclampsia	3
Chronic nephritis*	3
Beri-beri	3
Placenta praevia	2
Accidental haemorrhage	2
Acute yellow atrophy of liver	2
Acute phthisis	2
Secondary post-partum haemorrhage	1
Puerperal sepsis	1
Pulmonary embolism	1
Valvular disease of heart	1
Myocarditis and chronic bronchitis	1
Broncho-pneumonia and empyema	1
Tuberculous meningitis	1
Cerebral haemorrhage†	1
	25

* Probably due to pregnancy toxaemia.
† Patient admitted before labour with hemiplegia.

Excluding the ten deaths from diseases not directly connected with pregnancy, the percentage of deaths was 0.9. It may be mentioned that in the two cases of placenta praevia and of accidental haemorrhage the patients were moribund on admission, and that one of the patients with eclampsia died before labour during her first fit after admission. Most of the deaths—four from haemorrhage and eight from toxaemic conditions—might have been prevented if medical advice had been sought earlier. Increased confidence in ante-natal treatment should do much to decrease the death rate in future.

I am indebted to Dr. R. M. Gibson, medical superintendent of the Alice Memorial and Affiliated Hospitals, for permission to publish this review of work done in the Maternity Hospital.

PATENTS AND DESIGNS

REPORT OF DEPARTMENTAL COMMITTEE

The report of the Departmental Committee on the Patents and Designs Acts and practice of the Patent Office was issued on March 31st (Cmd. 3829, H.M. Stationery Office, 1s. 6d.). The minutes of evidence taken before the committee will be published in the course of the next few weeks.

The committee was appointed by the Board of Trade in May, 1929, to consider and report whether any, and if so what, amendments in the Patents and Designs Acts or changes in the practice of the Patent Office are desirable. Its members were Sir Charles Sargant (chairman), Mr. H. Ballantyne, Mr. H. A. Gill, Mr. E. H. Hodgson, Sir Herbert Jackson, F.R.S., Sir William Jarratt, Mr. Fearnley Owen, Mr. J. G. Weir, and Mr. J. Whitehead, K.C.

In the course of its inquiry the committee heard oral evidence by witnesses on behalf of the following, among other bodies: British Medical Association, British Science Guild, Chartered Institute of Patent Agents, General Council of the Bar, International Association for the Protection of Industrial Property (British Group), Joint Chemical Committee set up by the councils of a number of chemical institutions, Law Society, and Medical Research Council. Oral evidence was given also by several witnesses on their own behalf, and a large number of observations and suggestions in writing were received from various associations, bodies, and persons.

COMMITTEE'S FINDINGS AND RECOMMENDATIONS

The report is divided into three parts: (1) patents; (2) designs; and (3) general; and contains a summary of the committee's main recommendations.

The committee finds no general demand for any alteration of the basic principles underlying the existing law in this country in relation either to patents or to designs, but recommends a large number of amendments in the Acts, some of which it regards as important and such as to justify early legislation. Among the more important recommendations are the following:

1. An extension of the area of the official search as to the novelty of inventions for which patents are sought. The committee recommends the adoption of a scheme by which the statutory duty now imposed upon the Patent Office of searching through the specifications of British patents published within the previous fifty years should remain, but the search would not necessarily be restricted to those documents. The examiners would be at liberty, acting under the directions of the comptroller, given either generally or in any particular case or class of cases, to make search in any other documents (including foreign specifications) or books which might offer any prospect of containing anticipations of the invention in question. The committee came to the conclusion that such a search, under well-informed direction, would be as adequate and useful as that undertaken by any other country.

2. Drastic amendments of Section 32A (which deals with the power of the court in infringement actions to grant relief in respect of particular claims) in order to avoid or mitigate the difficulties and abuses that have arisen as a result of the enactment of the section by the Patents and Designs Act, 1919.

3. Strengthening of the law relating to groundless threats of legal proceedings in regard to patents.

4. An amendment of the law in order to remove the grievance which exists among inventors in the fields of chemistry, medicine, and food, that invention in these fields is being unduly hampered by reason of the operation of Section 38A (1) of the Acts.

5. The appointment of a judge of the High Court as the tribunal for hearing those appeals from the comptroller in patent cases that are now heard by the law officer. The committee further recommends that the persons who at present have audience before the law officer should have audience before the judge, and that these changes should not constitute these proceedings High Court proceedings.

PROPOSALS REJECTED

Among the more important proposals which were placed before the committee in evidence, but which it does not recommend for adoption, are:

(*a*) A proposal to introduce into the industrial property laws of this country a new form of monopoly in respect of "useful designs" or so-called "short-term patents." The committee's conclusion is that the risks of hampering industry outweigh the possible advantage to individuals from introducing such a form of protection.

(*b*) A proposal that medical patents should in future be dedicated to the public and administered by a State department. The committee came to the definite conclusion that no sufficient case had been made out for any compulsory dedication, and that such an alteration of the law would operate adversely to the British fine chemical industry and discriminate unfairly against research workers in this country.

(*c*) A proposal that the jurisdiction of the comptroller should be extended in order to enable him to try comparatively simple patent actions in regard to infringement and invalidity. Although the majority of the committee were opposed to the suggestion, a substantial minority favoured such an extension of the comptroller's jurisdiction, mainly because of the need for providing some less costly method of settling disputes relating to patents than at present obtains.

Scotland

Scottish Vital Statistics

The quarterly return of the Registrar-General for Scotland for the quarter ending December 31st, 1930, has just been issued, and includes a preliminary statement of the statistics for the past year. The vital statistics for the year show a birth rate slightly higher than that of the previous year, a marriage rate which remains the same, and a death rate which is lower than in the previous year, and lower than the average of recent years. The birth rate was 19.3 per 1,000, which is 0.3 more than that for the previous year, but 2.9 less than that of the preceding ten years. The death rate was 13.2, which was 1.3 below the rate for 1929 and 0.6 lower than that for the preceding ten years. The infantile mortality rate of the year was 83 per 1,000 births, which is 4 less than that of the previous year, and 7 less than the average of the preceding ten years. The death rates both from all forms of tuberculosis and from respiratory tuberculosis were the lowest yet recorded. The death rate for all forms of tuberculosis was for the first time below 90 per 100,000, and that for respiratory tuberculosis was 62 per 100,000, which is 5 less than in the previous year, and 14 less than the average of the past ten years. Deaths from malignant disease, on the other hand, showed the highest number yet recorded. The births of 23,087 living children were registered during the fourth quarter, and the deaths numbered 15,985. With regard to the ages at death, 16.9 per cent. were children under 5 years, 40.5 per cent. were persons between 5 and 64 years, and 42.6 per cent. were persons aged 65 and over. As to the causes of death during the quarter, 3.1 per cent. were due to the principal epidemic diseases, of which whooping-cough, diphtheria, and the diarrhœas of childhood caused the greatest part. Malignant disease had been responsible for 11.3 of the total deaths, tuberculosis for 6.1 per cent., pneumonia for 9.2 per cent., bronchitis for 6.1 per cent., and violence for 4.5 per cent. The deaths due to diseases and accidents of pregnancy numbered 157, equivalent to a death rate of 6.8 per 1,000 registered births, which was 0.1 more than in the previous quarter and 0.9 more than in the fourth quarter of the previous year. Deaths due to accidents with motor vehicles numbered 197.

Medical Services in the Highlands and Islands

Under the auspices of the Institute of Public Administration, an address was recently delivered in the City Chambers, Edinburgh, by Dr. A. Shearer of the Department of Health for Scotland. Councillor Mrs. Morison Miller, chairman of the Public Health Committee of the Edinburgh Town Council, presided, and remarked that the Highlands and Islands Medical Service was concerned with a population of 320,000 scattered over an area of ten million acres. Dr. Shearer said that no more humane or beneficent social service existed anywhere in the Empire, and the money expended upon it had gained a better return than that of any similar fund. In 1850 the Royal College of Physicians had appointed a committee to inquire into the number of medical practitioners in the northern counties of Scotland, and to ascertain whether there was much complaint in regard to the difficulty of obtaining medical aid. It had been found that out of 155 parishes, 62 only were adequately supplied with medical practitioners, 52 were partially supplied, while 41 parishes were hardly ever visited by a medical practitioner. It was estimated that 124,000 people received practically no medical assistance. Owing to poverty, two-thirds of the people paid nothing for medical attendance, and elsewhere the ratio of non-paying to paying patients was 19 to 1. One practitioner in a parish of 5,000 people stated that he did not receive more than £5 annually from private patients. On the passing of the National Health Insurance Act in 1911, a great step forward had been taken, and this was followed by the Highlands and Islands Medical Service Act, which did something to remedy the totally inadequate medical and nursing services that prevailed. A scheme of grants to medical practitioners had then been put into operation, enabling the service of doctors to be brought to the humblest homes in any part of the Highlands at

low uniform fees. These fees were fixed at a maximum of 5s. for the first visit and 3s. 6d. for subsequent visits. In paying a tribute to the work of doctors in the Highlands and Islands the lecturer said he doubted if the great hardships which these doctors had to contend with in treating their widely scattered patients were generally appreciated.

Aberdeen Spring Graduation

At the spring graduation ceremony at Aberdeen University, held in the Hall of Marischal College on April 1st, the recipients of the honorary degree of Doctor of Laws included Sir Leonard Hill, M.B., F.R.S.; Sir Frank Edward Smith, secretary of the Royal Society; Charles Robertshaw Marshall, M.A., M.D., emeritus professor of materia medica in the University of Aberdeen; and Sir J. Arthur Thomson, M.A., LL.D., emeritus professor of natural history, University of Aberdeen. The degree of M.D. was conferred upon four graduands, and the M.B., Ch.B. upon twenty-one. In his address Principal Sir George Adam Smith remarked that although there had again been a drop during the winter session in the number of arts students, the number in medicine had increased from 296 to 332. With a view to improving the medical curriculum, it had been decided that all new students in medicine should begin their courses in October. Aberdeen, he said, had been selected as the centre of distribution for the North and North-East of Scotland of the radium belonging to the National Radium Commission, and arrangements for the use of the radium had been made with the Royal Infirmary and of radon in the natural philosophy department at Marischal College. A new lecturer on malignant diseases had been appointed.

Glasgow Samaritan Hospital

At the annual meeting of the Royal Samaritan Hospital for Women, Glasgow, held on March 30th, Sir John Stirling Maxwell, Bt., who presided, recalled that he had attended a meeting of this hospital in 1891, when it was mentioned that 593 in-patients and 508 out-patients had been treated. Since then the figures had increased enormously; last year the number of in-patients was 3,013, and of out-patients 5,078. These figures exceeded the total of the previous year by 749. In regard to finance, the ordinary income amounted to £16,024, but showed a decrease of £508 as compared with that of the previous year. Employee subscribers contributed £6,857—about £20 less than the receipts last year from the same source. In seconding the adoption of the report, the deacon convener said that they were passing through a time of great depression, and the donations might be somewhat decreased in consequence for the next year or two, but he did not think that there was any cause for being disheartened about the ultimate success in carrying on this good work.

Edinburgh Post-Graduate Courses in Medicine

The syllabus for post-graduate courses in medicine, organized by a committee representing the University and the School of Medicine of the Royal Colleges at Edinburgh, has just been issued. The series of courses will begin this year on July 13th, with a course on obstetrics, gynæcology; and diseases of children, which continues till August 8th, and is to be conducted in the Maternity Hospital, the gynæcological wards of the Royal Infirmary, and the Royal Hospital for Sick Children. It is to be followed by a general practitioners' course, which lasts from August 10th to September 5th, and includes instruction on applied anatomy, medical clinics, and clinical demonstrations, surgical out-patients, and surgical clinics, clinics on gynæcology and infectious diseases, and on special subjects such as diseases of children, diseases of the eye, and dermatology. Concurrently with the general practitioners' course there is a general surgical course for those specially interested in surgery; in addition to surgical clinics in the Royal Infirmary and Royal Hospital for Sick Children, this course includes instruction upon applied anatomy, diagnosis of renal disease, abdominal surgery, surgical pathology, surgical physiology, radiology, etc. A special feature of these courses is that on one day each week cases of medical and surgical interest will be exhibited for the purpose of promoting discussion. There are also special courses which may be arranged for limited numbers upon the pathology of the nervous system, vaccine therapy, diagnostic methods, diseases of the blood, *x*-ray physics, ultra-violet radiations, and ophthalmoscopy. A detailed syllabus, with information about fees, may be obtained from the secretary, Post-Graduate Courses in Medicine, New University Buildings, Edinburgh.

New Edinburgh Professor

The curators of patronage of Edinburgh University have appointed Professor James Couper Brash, *M.C.*, to the chair of anatomy in the University of Edinburgh, in succession to Professor Arthur Robinson, who resigns at the end of the current academical year. Educated at George Watson's College, Edinburgh, and the University of Edinburgh, Professor Brash graduated M.A. in 1906, B.Sc. in 1908, and M.B., Ch.B. in 1910. After acting as demonstrator of anatomy at Edinburgh University, he became demonstrator and assistant in the anatomical department at the University of Leeds, and was subsequently appointed professor of anatomy at Birmingham University. He has carried out much research work in the embryology and development of the jaws and teeth, and has contributed extensively to the literature of the subject.

Church of Scotland Deaconess Hospital

The thirty-sixth annual meeting of the Church of Scotland Deaconess Hospital, Edinburgh, was held on March 26th, under the presidency of Lord Sands, chairman of the hospital board. The number of patients treated in the hospital during the year was 941—240 more than in the previous year, and a record number for the hospital. Of these, 388 were children. As to maternity cases 98 were attended from the hospital, and the out-patient department dealt with 7,573 patients, compared with 6,703 in the previous year. The total number of cases treated by the hospital during the year was 8,705, as compared with 7,813 the preceding year. Total receipts amounted to £6,319 and the expenditure to £6,166. During the past year £4,000 was given to the hospital in legacies and donations.

England and Wales

Royal Victoria Infirmary, Newcastle

The annual meeting of the Royal Victoria Infirmary, Newcastle-on-Tyne, was held in the city hall on March 28th, under the presidency of the Lord Mayor. The returns for the year show an increase in the number of patients treated, the demand for in-patient treatment being in excess of the supply of beds. Schemes for increased bed accommodation, including a complete orthopædic block, are under consideration. The pay-bed section of the hospital is nearly complete. Approximately £140,000, including the generous gift of £25,000 from Sir Walter Runciman, has been subscribed towards the estimated capital expenditure of £150,000 necessary to carry out this work. At the Royal Victoria Infirmary, as at many other hospitals, an attempt is being made to

confine the activities of the out-patient department to purely consultative work, adequate medical provision having been made for the greater number of out-patient cases under the National Health Insurance Acts and the Local Government Acts. An agreement has been made with the National Radium Committee whereby the hospital will be constituted the national radium centre for Newcastle and district. The income of the hospital amounted to £100,257, and expenditure to £93,537.

Infectious Diseases at London Council Hospitals

The Central Public Health Committee of the London County Council has been considering what steps can be taken to prevent patients who enter a Council hospital suffering from one infectious disease contracting some other infectious disease at that hospital. It is stated that the prevention of cross-infection in infectious diseases hospitals has always presented great difficulty, since cases are frequently admitted in a latent or incubation stage of secondary disease, the detection of which is impossible before the disease develops. Although these patients are at once isolated, the other patients in the ward have, in the meantime, been exposed to risk of infection. The only effective means of prevention would be to place every infectious patient for the first few weeks of his stay in hospital in a separate room, an impracticable arrangement in London, and unnecessary so far as the vast majority of patients admitted are concerned. For some years the Metropolitan Asylums Board pursued the policy of enlarging isolation accommodation for these and other doubtful cases, and had been advised that such accommodation should comprise 33 per cent. of the total beds. The execution of schemes for converting large wards into separate chambers or cubicles has been deferred, however, pending the result of an experiment, suggested by the Ministry of Health, at the South-Eastern Hospital, New Cross. This experiment, which started in 1929, consists in dividing two of the wards in such a way as to permit of adequate cross-ventilation. These small wards have been in use now for just over a year, and have proved satisfactory as regards ventilation and practical working, and also from the point of view of medical results. The Central Public Health Committee proposes to inform the Ministry of Health that the schemes for provision of additional isolation accommodation at other hospitals, so far as they take the form of subdivision of existing wards, shall be on the same lines as at the South-Eastern Hospital. The system involves a considerable diminution in the number of beds; at the South-Eastern Hospital the number has been reduced from forty-four to thirty. Statistics as to the decrease of cross-infection are not yet available, as no hospital has yet its full proportion of isolation beds, but the matter will be reviewed again in a year's time, when it is hoped that experience will be sufficient to enable reliable deductions to be drawn.

Harrow Hospital Extensions

A scheme of enlargement, to cost £50,000, is in progress at Harrow Hospital, Roxeth Hill, Middlesex, and the new buildings are to be opened by the Duke and Duchess of York on May 6th. The Stuart Memorial extensions, by which name they will be known, embody some interesting innovations in planning, engineering, and administration, which have attracted the attention of the hospital world, and nearly eighty representatives of other hospitals were present recently at a visit of inspection. Special methods have been installed for sound absorption, for the maintenance of an even temperature throughout the buildings, and for the arrangement of the new operating theatre, which carries out the most modern principles of design and ventilation. Adjoining the main theatre is a dark room to which appropriate cases can at once be moved when necessary. The air for the operating theatre enters clean and warm through oil filters, and there is provision for the rapid escape of ether. In the sterilizing room, which leads by an archway off the operating theatre, the sterilizers are built into a counter; the work is done by electricity, and there are no fumes. The control of the temperature of the hospital itself is also on modern lines: a system of panel heating is adopted which the engineers claim to be a perfect method of radiating heat on the principle of equalized distribution. This panel method, which eliminates the use of radiators, requires a temperature of only 100 to 105° F., as against a temperature for convection of 150 to 180° F., thus saving fuel consumption. Magnetic valves are set in little boxes here and there on the walls to permit of the regulation of temperature in a given space within a limit of 1° F., and thus maximum comfort and economy are assured. A new *x*-ray department is being constructed, at a total cost of £2,000. Other features of interest in the new extensions are electric lifts, capable of taking bed, patient, nurse, and attendants to all floors; a soiled-linen chute opening on each floor and delivering to the basement, so that no germ-laden linen needs to be carried through the corridors; running water in all the wards, with elbow levers in place of ordinary taps, thus leaving both hands free; and the provision for each bed of its own switchboard, for bed-light, bell, wireless headphones, and inspection lamp. The windows have rounded corners, and the doors are without panels, thus avoiding dust. All pipes are built into the wall and equipped with inspection doors. Altogether the Harrow Hospital, which was founded as a cottage hospital rather more than sixty years ago, will furnish a noteworthy example of modern construction and arrangement, adapted to the needs of a growing district which is now almost a London suburb. The beds will be increased in number from forty to seventy-five.

National Dental Hospital

A complimentary luncheon was given on March 28th at the Trocadero Restaurant by the staff of the National Dental Hospital—the dental department of University College Hospital—the occasion being the resignations of Drs. C. J. Ogle and James Maughan as honorary anaesthetists. Dr. J. L. Dudley Buxton, the subdean, after announcing with regret the absence of Dr. Ogle, pointed out how Dr. Maughan had quietly devoted himself to the work of the hospital for forty-three years. His classes in anatomy, physiology, pathology, and anaesthetics were successful, and always well attended, and he also took an active part in the life of the students, who elected him president of the Students' Society for many years in succession. He was editor of the hospital gazette from 1906 onwards, and by this means fostered a closer *rapport* between the hospital and old students all over the world. The toast to Drs. Ogle and Maughan, proposed by Dr. Buxton, was received with acclamation. Dr. Maughan, in replying, expressed sympathy with Dr. Ogle in his recent bereavement. One of his early impressions of hospital life was an interview in 1886 with Sir Benjamin Ward Richardson, who prophesied that the day would come when anaesthetists would recognize that hypervenosity of the blood constituted an important factor in the induction of general anaesthesia. Dr. Maughan reminded his hearers that the "National" had been the happy hunting ground of Sir Henry Head. At the time when Dr. Head pursued his researches there, two diagrams of "referred pain" areas were actually on the walls of the building. Dr. Maughan thanked the staff for the honour they had accorded to Dr. Ogle and himself, and expressed the belief that the hospital would always be an efficient training ground for dental students of pluck, energy, and tenacity of purpose.

British Spas Federation

At the half-yearly meeting of the British Spas Federation, held in London, many matters of interest were discussed. Bridge of Allan was admitted to membership. A special committee was formed with a view to investigating the possibilities of arranging for lectures on spa treatment at the leading hospitals in London and elsewhere. It was reported that the British Medical Association had approved a scheme for the treatment of friendly society patients at spas, and the necessary machinery was being set up immediately. The scheme allows for friendly society patients to take treatment at spas in the federation, for rheumatism and kindred troubles. Mr. W. J. Leist (Leamington Spa) was appointed secretary in place of Mr. J. E. Boddington (Buxton). Alderman Hacker (Bath), on behalf of the federation, expressed to Mr. Boddington thanks for the able manner in which he had carried out the duties of honorary secretary during the past three years, and handed him a silver tea service as a tangible expression of their appreciation.

Correspondence

HALLUX VALGUS

SIR,—The discussion on this subject induces me to contribute an experience of the operative treatment with the hope of establishing a procedure alternative to that of removal of the head of the metatarsal bone—namely, removal of a part of the first phalanx. This method is described by one of your correspondents, Mr. James Phillips; it is not mentioned in any of the modern textbooks on surgery, though it is described by the writers on orthopaedics.

A reference to the first description of the operation will, I am sure, be appreciated, and the experience here recorded may lead to its general adoption. Mr. Davies-Colley of Guy's read a paper before the Clinical Society on March 26th, 1887, on contraction of the metatarsophalangeal joint of the great toe (hallux flexus), published in volume xx of the *Transactions* (p. 165). He gives his views on the production of both deformities, and records successful cases of operation for hallux flexus. This method I carried out from the above date till the conclusion of my Army service in 1919. At the Lambeth Hospital, where both varieties are not uncommon, removal of part of the phalanx, even to one-half or two-thirds, is the invariable practice. The operation and its results are well illustrated by the following case.

Colonel C., a tall and heavy man, aged 62, suffered from hallux flexus of both great toes. The rigidity hampered his walking, and prevented his playing golf. The articular surface of the phalanx was removed by a saw through a dorso-lateral incision on April 6th, 1909; the marginal osteophytes, though of unusual size, were not removed. In the final position the toe was a little cocked up, just enough to permit easy walking, while the movement in the joint allowed a little further play. He was so pleased with the result that he desired a similar operation on the other toe, which was done in November, 1910. On this occasion the marginal outgrowths were removed. The overlying tissues, however, became adherent to the bone, causing some tenderness and temporary restriction of movement. Some time later, on examining the toe first operated upon, it was found that the osteophytes had disappeared, showing that removal was unnecessary. The final result was excellent; he walked in comfort and played his golf.

The same operation is applicable to hallux valgus, though a much larger removal of bone is necessary to bring the toe into line. So long as the head of the metatarsal and the sesamoids are not interfered with, one-half or more of the phalanx may be removed without impairing the result. Mr. Phillips sets out briefly the merits of this operation, and the disadvantages following removal of the head of the bone in cases of valgus. Two points as to detail. The incision should be as Davies-Colley directs: one and a half inches long, at the junction of the upper and inner surfaces of the joint. Personally, I prefer division with a saw, for which purpose the phalanx can easily be turned out if the incision be of sufficient length. It is interesting to note that one general surgeon, at any rate, has in recent times practised an operation first described forty-five years ago, which has remained almost unknown in the interval except to the immediate pupils of the surgeon who originated it, and to certain orthopaedic surgeons. Having myself carried out this operation on many occasions, and with excellent results, it may be hoped, from the experience recorded by Mr. Phillips and that mentioned at Lambeth, that the method will be generally adopted, and removal of the head of the bone abandoned.—I am, etc.,

London, March 31st. CHARTERS J. SYMONDS.

THE KELOID OVARY

SIR,—I have read Mr. T. C. Clare's contribution in the *Journal* of to-day's date with very great interest, not merely because of the arguments brought forward against my conception of the etiology of metropathia haemorrhagica, but because his article illustrates the attention which is being paid to the physiology and pathology of the human ovary. There are well-marked signs at the present day that the purely theoretical side of gynaecology is receiving recognition, and the few remarks I have to make on Mr. Clare's paper may perhaps be of some help.

I am afraid that I am in complete disagreement with Mr. Clare's views on the etiology of Krukenberg tumours. Some years ago I published a short paper on these interesting tumours, and concluded, mainly by a process of exclusion, that the cause was to be attributed to lymphatic permeation of the medulla of the ovary. Recently I have succeeded in demonstrating this process at work at a very early stage, and I believe that the findings are beyond criticism. These results will be published in due course. Meanwhile it may be of interest to know that it is relatively simple to demonstrate this mechanism in ovaries which are obtained at necropsy from cases of carcinoma of the stomach. The ovaries may appear normal to the naked eye, but microscopically they are often found to be invaded by carcinoma cells which lie in the lymphatics of the medulla. I am doubtful if Schauta's view of the etiology of ovarian metastatic tumours ever received wide recognition, although his opinions always demanded the greatest respect. The obvious objection to his view is the incidence of Krukenberg tumours after the menopause, when follicles have ceased to rupture in the ovaries.

The problem of the etiology of the necrosis of the endometrium in cases of metropathia haemorrhagica is much more difficult. I admit that the explanation I offered was in many ways purely hypothetical, but my excuse for this is the absence of reliable evidence of the physiological processes at work in normal menstrual necrosis. I have repeatedly emphasized my opinion that the exact etiology will never be known until further advances have been made in the physiology of menstruation. Until then the explanations that are put forward will be only approximate, and will be open to such objections as Mr. Clare brings forward. It seems to me, therefore, that the correct policy is to await patiently for these advances to be made rather than to debate the subject on pure conjecture. Mr. Clare's views are extremely interesting, but they are in many ways open to criticism. I am doubtful if anything will be gained by indicating these objections, for, as I have said, the basis of the discussion is not as yet one of mathematical precision.

I am extremely grateful to Mr. Clare for directing attention to my work, but I wish to make clear that the views I have expressed on the etiology are to be regarded as what I believe to be the best explanations of the established facts. I am quite prepared to acknowledge that they may have to be modified when more becomes known of the physiology of menstruation.—I am, etc.,

St. Bartholomew's Hospital, March 28th. WILFRED SHAW.

THE ELECTROCARDIOGRAM

SIR,—I marvel at the studied moderation of the letters of Dr. C. Blaxland Levick and Dr. Jenner Hoskin in response to the reactionary leading article published on March 7th. For my part I find it difficult to comment temperately on it, even after allowing myself three weeks in which to cool down.

I must confess that I have no experience as to what happens when my electrodes are "in contact with a circular pad of filter paper moistened with saline"; nor have I investigated "the distribution of potential in a linear conductor, consisting of a thread previously moistened with saline and supplied with stationary doublets in the form of pairs of non-polarizable electrodes." But, in common with other cardiologists all over the world, I have for the last eighteen years been attempting to correlate the electrocardiographic and clinical findings of many hundreds of patients with their after-histories, and, like my brother cardiologists, have come to the conclusion that an electrocardiogram is often an invaluable, and sometimes an indispensable, factor in diagnosis and prognosis. For example, an electrocardiogram taken during the course of what appears to be quite a trivial rheumatic infection sometimes reveals an entirely unsuspected active carditis, with the result that a longer rest is enjoined on the patient than would otherwise have been the case, possibly saving him from subsequent invalidism. In my opinion, every case of mild or subacute rheumatism should be examined electrocardiographically.

The diagnosis of a severe coronary occlusion is usually easy on purely clinical grounds (and I would like here to point out that the "vociferous adherents" of electrocardiography in the United States were fully conversant with the clinical picture of coronary infarction for several years before more than a select few of the countrymen of Mackenzie and Lewis became aware of the possibility of the clinical recognition of this common accident). But the less extensive and the more insidious infarctions are not always easy to diagnose, and time after time an electrocardiogram enables us to say with conviction that a patient is suffering from a coronary infarction, in spite of his symptoms being not at all alarming. Here, again, a few weeks in bed for such a patient may be literally a matter of life or death. There must be hundreds of lives lost in this country every year owing to slight attacks of coronary occlusion being diagnosed as angina, or, more probably, as "gastritis," and allowed to return to work with a necrotic myocardium. Many of these lives would be saved by electrocardiographic examination.

Finally, I would like to refer to the cases of slow myocardial degeneration due to coronary arterio-sclerosis. Here there is no doubt at all that the finding of a bundle-branch block, or of less gross electrocardiographic abnormalities, adds considerably to the gravity of the prognosis. Any experienced cardiologist can produce dozens of instances of the unsuspected finding of a pathological electrocardiogram, where the bad prognosis then given, in spite of negative clinical findings, has subsequently turned out to be justified. Moreover we frequently have the opportunity of observing progressive changes in the electrocardiogram year by year, and experience teaches us that the galvanometer is of assistance to us in expressing an opinion as to whether a degenerative condition is rapidly progressive or not.

I am fully conscious of the shortcomings of electrocardiography, and of the possibilities of its abuse. I admit that from time to time we find a normal electrocardiogram in cases where the myocardium is diseased, and that, very occasionally, a grossly aberrant electrocardiogram may be compatible with long years of good health. As in all other branches of medicine, the clinical history is of paramount importance in cardiology, and the physical signs are subsidiary. But I submit that to withhold electrocardiographic examination from a patient suffering from anginal symptoms, or presenting other evidence of myocardial degeneration, is to-day unjustifiable, to put it mildly.—I am, etc.,

London, W.1, March 30th. MAURICE A. CASSIDY.

DIVERTICULA OF THE COLON

SIR,—Even after most careful scrutiny of the colon from various angles, as advocated in the excellent paper on diverticula of the colon by Mr. Lockhart-Mummery and Dr. Graham Hodgson in the *Journal* of February 28th (p. 525), many diverticula will escape detection unless the patient is examined twenty-four hours after the opaque enema has been administered. In fact, the investigation cannot be considered complete unless this second examination is included.

The conclusion that those diverticula which show a "ring-like" shadow contain concretions is, I think, not quite correct. In the first place, the opaque emulsion is hardly likely to gain entrance to a diverticulum already full, and one has seen diverticula which, fully filled at the time of the enema, show these ring-like shadows in twenty-four hours; so one concludes that in most cases this outlining effect is due to the barium emulsion adhering to the inner wall of the sac.—I am, etc.,

S. GILBERT SCOTT, M.R.C.S.,
London, W.1, March 31st. L.R.C.P., D.M.R.E.

SIR,—I wish to draw attention to a possible misconception that may arise from the very interesting description of diverticula of the colon in the *Journal* of March 28th.

Emphasis was there strongly, and deservedly, laid upon the value of radiological diagnosis of the condition, but a danger arises from the importance given to radiographic demonstration. This was doubtless unintentional, as I feel sure that Dr. Graham Hodgson carries out a complete screen examination of each case. The article does, indeed, draw attention to the value of screening, but it also insists upon the necessity of films being exposed in various positions of the patient. It is from this insistence that misconception may arise, since the surgeon may be led to assume that a sufficient number of such exposures is all that is necessary. On the contrary, the colon can be much more conveniently inspected in all diameters by screen observation, and such observation is essential for differentiation of spasm from organic change. No number of films can so effectively make this differentiation, and the commonest errors in radiological observation of the colon are due to reliance upon films, in the absence of screen observation or the interpretation of an experienced radiologist aware of the possible fallacies.

This letter in no wise detracts from the value of the contribution referred to; on the contrary, it is a tribute to the excellence of the demonstration that such danger of its over-emphasis should be feared. Radiology must, however, never be allowed to appear as a matter primarily of skilled technique. This is certainly called

for, but, above all else, as in other observations in medicine, a skilled and experienced interpretation is required.—I am, etc.,

Radlett, March 31st. JOHN MUIR, B.Sc., M.B., Ch.B.

TREATMENT OF GASTRIC AND DUODENAL ULCER

SIR,—Mr. Rendle Short's survey of the treatment of peptic ulcer contains a few points of special interest to radiologists. Both Mr. Rendle Short and Mr. Lake have found gastric ulcers still active at operation which were absent on the radiograms, thus suggesting their recovery. If, as I suspect, a niche was still present in these cases, its absence on the film was due either to an omission on the part of the radiologist to make a preliminary screen examination before exposing his film (to ensure correct position), or, if he did screen, to an imperfect knowledge of technique and quite easily from failure to see the small niche, for skill in screening is only obtained after long and patient practice. When the niche has gone the real difficulty begins. Personally, I do not know when the granulations in the ulcer crater are covered with epithelium —some day I may know. At present I find it easier to record progress in the healing of a duodenal ulcer than a gastric ulcer.

My observations on duodenal ulcer after gastro-enterostomy show an ulcer crater present in most cases even ten years after operation. It is true that most of these cases are sent to me because of symptoms, but I do see patients sometimes without gastric symptoms where the ulcer crater is still visible. Moreover, during the systematic medical treatment in hospital of duodenal ulcers I find radiological evidence present long after symptoms have subsided, and occult blood tests of the stools are decidedly negative, clearly indicating that the healing process is very much slower than is currently believed. The final *x*-ray evidence I rely upon is the presence or absence of the crater pool. One such case I watched for fifteen to eighteen months with the aid of six barium meals. Only once during this period was I unable to find the crater. This was quite an early case in a young woman about 22 years of age. At the end of this period she was not greatly improved radiologically. To-day she still has her ulcer, with symptoms.

I see many duodenal and fewer gastric ulcers. The latter yield more readily to treatment, but the former appear to require very prolonged treatment after all symptoms have disappeared.—I am, etc.,

London, W.1, March 31st. JOHN R. WYLIE.

TREATMENT OF DETACHMENT OF THE RETINA

SIR,—In the *Transactions of the Ophthalmological Society of the United Kingdom* for 1931, just published, I note that Professor J. Gonin says, on page 535: "... It may appear curious that all the author's communications on that matter [that is, detachment of the retina] remained unknown to the English-speaking world until the International Congress in Holland." For the credit of English medical journalism, may I be allowed to point out that, in an abstract in the *Medical Annual* for 1929 (p. 412), written in the summer of 1928, I gave the essential points of Gonin's treatment so far as were then available, and a reference to his original paper in the *Annales d'Oculist.*, 1927. Knowing that in some parts of Europe we English are supposed to be somewhat insular and ignorant of what is being done elsewhere, I think it well that this statement should not be allowed to pass unchallenged.—I am, etc.,

Clifton, Bristol, March 29th. A. E. J. LISTER, M.B., B.S., F.R.C.S.

GONOCOCCAL RHINITIS

SIR,—In reply to Dr. A. Scott's query (March 28th, p. 561), might I say that there should be no difficulty in growing the gonococcus from a specimen of nasal pus, provided a suitable medium, such as hydrocele agar *p*H 7.5), be used. On this medium the gonococcus grows relatively freely in spite of severe competition by "secondary organisms." Should the growth of the latter be predominant, the gonococcal colonies may easily be seen by means of the pink coloration produced by the oxidase reaction, and thus may be subcultured for further investigation.—I am, etc.,

I. N. ORPWOOD PRICE

The Whitechapel Clinic, Mile End, E.1, March 30th.

Obituary

JOHN ANDERSON, M.A., M.D., B.Sc., M.R.C.P., D.T.M. AND H.

Head of the Medical Division, Henry Lester Institute for Medical Research, Shanghai; late Professor of Medicine, Hong-Kong University

By the death of John Anderson, at the early age of 52, the cause of medical education in China has suffered a severe loss. Though comparatively unknown in this country, he was widely esteemed in the East, and, indeed, in time to come it may be acknowledged that the part he played in recent years will rank as a pioneer effort in that great and developing country.

Born in Glasgow in 1879, he received his early education in that city. Graduating M.A. in 1901, he devoted so much time to advanced zoology, a branch of study to which at first he intended to devote himself, that he did not qualify till 1907, in which year he took his M.B., Ch.B., but did not proceed to the degree of M.D. till thirteen years later. Having sufficiently equipped himself, he settled down in the town of Wallasey, near Liverpool, where he practised with considerable success till 1914. Indeed, his professional capabilities were rated so high in the neighbourhood that he frequently acted as consultant in Liverpool. At the outbreak of the great war he was soon gazetted to a casualty clearing station, and was drafted as medical officer to Gallipoli, where in the heavy work which ensued he soon showed his mettle, and afterwards became surgical specialist. His devotion to his unit, his powerful influence for good, and his authority over the men under his command were appreciated, but owing to his modesty and self-effacement did not gain official recognition. Many acts of gallantry were accredited to him and were known to his close friends. On one occasion he continued unperturbed to complete an abdominal operation while enemy bombs dropped around his operating tent, one of which exploded immediately above him and set the neighbouring structures ablaze.

Towards the end of 1917 Anderson began to evince a very keen interest in practical bacteriology and pathology as applied to field conditions in the advanced laboratories of the Egyptian Expeditionary Force. Having already acted as surgical and medical specialist, he now became an expert pathologist, and held commands of various field laboratories till the armistice. For two years after the cessation of hostilities he remained in Egypt and the Sudan, becoming a general consultant in medical matters to the Director of Medical Services. For this he was awarded a free tour round India, and, returning to England in 1920, he became a student, and subsequently demonstrator, at the London School of Tropical Medicine. Gaining the Wandsworth Scholarship, he accompanied Professor R. T. Leiper to British Guiana on a research in filariasis in 1921. He was responsible for the admirable

memoir (No. 7) of that research published by the School, and he executed the fine line drawings which illustrated it. Soon after the termination of this research he assisted in the helminthological department, and in 1925 was selected as professor of medicine to Hong-Kong University. There he achieved his chief work in remodelling Manson's university as a live thing. He directed and reorganized the teaching of medicine in a most able manner, so that almost the whole work of this department devolved on his shoulders. In addition, he was widely known in the town for his medical skill, so that he obtained a large consulting practice among the Chinese and Europeans. His extraordinary insight into the mind and character of the Chinaman, and his sympathy with his national aspirations, gained for him great popularity, and led indirectly to his appointment in 1930 as director of the Henry Lester Institute for Medical Research at Shanghai, for which a sum of over one million pounds had been bequeathed. To Shanghai, then, he proceeded late in 1930, and was successful in negotiations about the future status of this institution in the medical education of China. The plans of the institute were complete, and he was formulating schemes for research in the future, as visualized in a letter received by the writer on the very day of his death.

John Anderson possessed an exceptionally strong and sympathetic character, and there can be few men of his generation who inspired such sincere affection in everyone with whom he came into contact. He will long be remembered as a staunch friend, and as a brave and resourceful companion, one whose modesty and self-effacing character prevented him to some extent from securing those academic and scientific honours to which he could legitimately have aspired.

P. H. M.-B.

JOHN EDWARD THOMAS, M.D., C.M.

Senior Surgeon, Carnarvonshire and Anglesey Infirmary, Bangor

The death occurred at his home, Nantlys, Bangor, on March 24th, of Dr. J. E. Thomas, one of the best-known practitioners in North Wales, at the age of 62. The second son of the late Mr. W. Thomas, J.P., of Plas Newydd, he was educated at the University College of Wales, Aberystwyth, and at Edinburgh University, where he graduated M.B., C.M. in 1890, proceeding M.D. in 1900. After a period as house-surgeon to the Carnarvonshire and Anglesey Infirmary (where he was later to give so many years to devoted and enthusiastic service), he settled in Bangor, and soon established a large practice in the town and surrounding district.

From his earliest days Dr. Thomas had shown a marked inclination and aptitude for surgery, and it was therefore not surprising that when in 1910 he was appointed surgeon to the Carnarvonshire and Anglesey Infirmary a new era in the surgical work of that hospital commenced. At the termination of his twenty years' tenure of office in November last, the hospital committee, as a mark of the great appreciation of his services, took the unusual step of inviting him to continue as senior surgeon.

During the whole of the war Dr. Thomas was surgeon to the Military Hospital at Bangor. His reputation as a surgeon was such that for many years his colleagues throughout North-West Wales had availed themselves fully of his experience and operative skill. His surgical appointments included those of consulting surgeon to the Blaenau Festiniog and Portmadoc War Memorial Hospitals. He was a member of the court of governors of the University College of North Wales, and in addition to being medical officer to this College was also medical officer to the Normal College, Bangor.

Dr Thomas was always a keen and enthusiastic member of the British Medical Association, and was president of the North Wales Branch in 1925–26. His activities were not confined to his profession, for he was much interested in public work. He was an alderman of the Corporation of Bangor, and was mayor of the city in 1920-21. He was a justice of the peace for the county of Carnarvon, and sat regularly on the magisterial bench. He inspired confidence by his quiet simplicity and rectitude, and his unfailing kindness will always be remembered by his patients and friends. He is survived by his widow, three daughters, and one son, who is a surgeon in London.

Dr. SPENCER STAWELL CROSSE, *M.C.*, died suddenly from cerebral haemorrhage at Kudat, British North Borneo, on February 10th. He was the third son of the late Rev. Edward Ilbert Crosse, and was born at Long Wittenham, Berks, in 1888. He was educated at Clifton College, and Pembroke College, Cambridge, completing his medical curriculum at Guy's Hospital. He took his B.A. (Nat. Sci. Trip.) Camb. in 1909, and qualified M.R.C.S., L.R.C.P. in 1912. After serving as house-surgeon and house-physician at the Royal Berks Hospital, he joined the R.A.M.C. in the first week of the war, hurrying home from a holiday abroad to do so. During the greater part of the war he was on active service in France, chiefly with field ambulances or at casualty clearing stations, and received the Military Cross. At the close of the war he remained in the Army for another six years, and was stationed in India during a large part of this period. On leaving the Army he held various posts as medical officer in the Tropics, on the Gold Coast, in British Guiana, and in Borneo. He took the Diploma of Tropical Medicine in 1928, shortly before sailing for Borneo on his last appointment. A straight man in all his dealings, Spencer Crosse was greatly beloved by all who knew him. Of an easy-going temperament, he took the ups and downs of life in a true philosophical spirit. He was kind and tolerant, and always endeavoured to put the best interpretation on the actions of others. He was never pushful, and though he had brains above the average he preferred to exercise them in what immediately lay before him. His sudden death at a comparatively early age came as a shock to his friends, since, although he had spent many years in the Tropics, he had always appeared to enjoy excellent health.

The sudden death of Dr. JOHN STEELE, J.P., of South Bank, Yorkshire, came as a great shock to the people of Eston district, where for over forty years he was in practice. He was one of the oldest members of the British Medical Association in the district, surgeon to Eston Hospital, medical officer of health, and casualty surgeon to four large works in the district. A colleague writes: Dr. Steele was gifted with that medical instinct which only comes as the reward of knowledge and experience. His life was one of unbroken service, which he loved to give, and his work had become so much part of himself that he feared the day when he should have to withdraw from practice, having often been asked to do so by his friends and relations. His patients were all his friends, and to many he was their best friend. Among the flowers at the funeral were to be seen tributes from the poor, who had made a collection to show their respect to a man of so outstanding a personality. Evidence of the esteem in which the people of the district held him was shown by the fact that over 12,000 people lined the processional route.

The following well-known foreign medical men have recently died: Dr. JEAN BAPTISTE COPPEZ, professor of ophthalmology at Brussels from 1891 to 1905, aged 90; Dr. AUGUSTE SLOSSE, professor of physiological chemistry at Brussels; Dr. PAUL FRANGENHEIM, professor of surgery at Cologne and an authority on bone surgery, aged 54; Dr. GIULIO TUNO, a physiologist of Rome; Professor VOGT, a Moscow pathologist, aged 83; and Dr. FÉLIX POUSSINEAU, formerly accoucheur to the Hôpital Lariboisière, Paris, aged 88.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons will resume its sittings on April 14th, when the Vote for the Ministry of Health is to be taken in committee. The second reading of the Town and Country Planning Bill is set down for the following day. Mr. Snowden hopes to open the Budget on April 27th.

Yarmouth Naval Hospital Bill

The Yarmouth Naval Hospital Bill, which had already passed the House of Lords, came before the House of Commons on March 27th. Mr. AMMON, for the Government, recapitulated the history of the hospital, and explained the legal doubts which the Bill was intended to resolve. The hospital at present contained 57 ordinary naval patients and 62 naval great war patients, whose cost of maintenance was borne by the Ministry of Pensions. The normal accommodation was for 213, but could be increased to 260 without structural alteration. If the Bill passed, the Ministry of Pensions would probably transfer 100 to 130 of their patients from other institutions. Up to the present no voluntary patients had been received at Yarmouth, but the Bill made provision for this. With regard to the indemnity clause against any legal action arising out of past use of the hospital, Mr. Ammon said that those in charge and their subordinates had acted in good faith and in the public interest, and should be protected.

Mr. MACPHERSON said there was disquiet in the country in regard to this Bill. So far as he knew the Army had no such institution, and never had had. The Admiralty had run this institution in disregard of the existing lunacy laws. Medical treatment and diagnosis of insanity required special care and skill, but under the Bill there was to be no diagnosis by a specialist. It would be diagnosis by two ship surgeons. There was nothing in the Bill to secure that this institution would be under the general Board of Control even for inspection.

Mr. KINLEY, in criticizing the Bill, said that the House was asked to agree that, because a man had been attached to the Admiralty, he must not be permitted treatment for his mental sickness near his own home.

Major TRYON remarked that Mr. Kinley now asked for ex-service men to be put into asylums with the rest of the community—a thing which the ex-service men's organizations had striven to prevent. To meet the demand of those organizations the Ministry of Pensions had started special hospitals at the Old Manor, Salisbury, and at Kirkburton, near Huddersfield, to which certified ex-service men could go if their families so desired. It was found that many friends and relations of these unhappy men did not like them taken away from the neighbourhood, and he thought it was the case that the Ministry of Pensions might not be able longer to retain one or two of these special hospitals, which had worked well. The Ministry might be glad to avail itself of the Yarmouth Hospital, but, if so, it would be fairer for that Ministry to tell the House that it wished to have the hospital, and why. He added that the Ministry of Pensions fought against certification wherever possible, and its medical staff had found methods which would be of use in mental cases throughout the world.

Mr ERNEST BROWN moved, and Mr. SHAKESPEARE seconded, the rejection of the Bill.

Dr FREMANTLE thought much could be said in favour of closing the Yarmouth Hospital altogether. It was infinitely better that patients belonging to the Services should be treated as if they were civil patients, and the cost charged to the proper authority. That was the procedure generally adopted in the Army. There was a good deal to be said, however, for keeping a separate naval hospital, if patients and their friends preferred it as he believed they did. As far as he could make out the Yarmouth institution was not half full, and he imagined the Bill was intended to fill vacant places and spread the overhead charges. A great increase of institutions for mental treatment was bound to occur under the Mental Treatment Act and the Local Government Act, 1929. Would it be right to bolster up an institution which was built one hundred years ago or so? He would agree to the Bill being passed if assured that it was intended to improve Yarmouth Hospital in the interests of the patients.

Mr. AMMON said the hospital had always been a voluntary one, and that was made explicit in the Bill. There was no question of compelling anyone to go there against his will or against the will of his friends or relatives. The House was dealing only with long-service men. A pensioner certified as of unsound mind would be sent to the nearest hospital, and would afterwards be removed to Yarmouth unless objection had been raised. The Bill had been submitted to the Scottish General Board of Control, which was satisfied. The Bill was earnestly desired by persons connected with the Navy. Next August Kirkburton, under the Ministry of Pensions, would close down, and that Ministry was anxious that the Yarmouth Hospital should be in readiness for this, so that the patients might then be transferred. The Board of Control had advised the Admiralty to retain the hospital, and Sir Hubert Bond was on the board of governors. Medical officers at Yarmouth had all had experience in civil mental institutions, and were chosen with special regard to their qualifications. There was no question of a man being put into Yarmouth Hospital, certified as cured, and put back into the Navy. He would be invalided out of the Navy. If there was any difficulty about a right of appeal to the Board of Control, he would look into it, and it could be met in committee

The Bill was then read a second time without a division and sent to committee of the whole House, where Mr. KELLY moved an amendment to ensure, in Clause 1, that no man should be certified from the Navy to the Yarmouth Hospital save with the certificate of an additional medical practitioner not in the service of the Admiralty. He contended that stronger evidence was required than the certificate of two doctors in the service of the Admiralty. Mr. AMMON, for the Admiralty, asked Mr. Kelly to withdraw the amendment. There was no compulsion on anyone to enter the hospital. Even greater precautions were taken than if the patient was to go into a civil mental hospital. When mental affliction was noticed in a naval rating the man would be taken into the sick bay for observation. The surgeon could not deal with the case out of hand, but could send the man to a naval hospital at Chatham, Devonport, or Haslar. If the authorities were of opinion that the man was mentally afflicted the Admiralty would send him to a consultant in mental diseases, who would be Sir Hubert Bond. If there was no doubt, the man would be certified by two medical officers of the hospital, and the whole set of reports sent to the Admiralty for the man to be invalided out of the Service. In the meantime, the man's relatives would be communicated with, and could allow him to go to the Yarmouth Hospital, or could transfer him to any other mental hospital. All these steps were taken before a man was certified.

Mr. KELLY withdrew his amendment, and the clause, with subsequent clauses, was accepted. A new clause was added making any misstatements on certificates under the Bill a misdemeanour. The Bill was then reported to the House and passed forthwith through report stage and third reading without debate.

Prices of Drugs

On March 30th Mr. GRAHAM moved the second reading of the Consumers' Council Bill. During the debate Mr. HERBERT GIBSON expressed a hope that, under the power which the Bill would give, the Consumers' Council would deal with the price of aspirin tablets. He cited an advertisement which suggested that retailers could make 102½ per cent. profit on a brand of these. Mr. LOVAT FRASER said that on no class of article supplied to the public were more unjustifiable profits made than on some articles supplied by druggists. He asked if the Consumers' Council would consider the prices of embrocation, camphorated chalk, and sodamint. Mr W R SMITH, for the Government, said the House had examples that evening of the profits made from a chemical product aspirin, for which a fixed price was asked. The Government objected to a system of price-fixing against the interests of the consuming public

The Bill was read a second time by 263 to 220.

Venereal Disease in the Navy

In reply to Dr. Fremantle, on March 25th, Mr. AMMON said reductions (or increases) in the incidence of venereal diseases in the Navy were shown in the following figures. In 1924 there were 5,987 cases, a ratio of 68.32 per 1,000 of strength, and a decrease on the previous year of 10.19; in 1925 there were 5,412 cases, a ratio of 60.16 and a decrease of 8.16; in 1926 there were 5,184 cases, a ratio of 57.18 and a decrease of 2.98; in 1927 there were 5,341 cases, a ratio of 57.28 and a 0.10 increase; in 1928 there were 5,160 cases, a ratio of 56.81, a 0.47 decrease; in 1929 5,342 cases, a ratio of 61.94 and a 5.13 increase. Comprehensive education schemes were in force in the training establishments. In the general depots all new entrants received special instruction. In boys' training establishments very special care was taken to ensure adequate and suitable instruction in sex hygiene. This instruction formed part of the general scheme of moral training, and was carried out in close co-operation by the divisional executive officers, the chaplain, and medical officers. Thorough instruction, especially with regard to venereal diseases and their dangers, was imparted to those boys before they were drafted to sea-going ships.

Opium

On March 30th Mr. SHORT informed Mr. Campbell that the production and distribution of opium would not be included in the purview of the conference on the limitation of the manufacture of dangerous drugs, to be convened by the League of Nations at Geneva next May.

Mr. SHORT, replying to Commander Bellairs on March 30th, said that the Home Secretary was not aware that quantities of opium and its derivatives were sent from Russia into China. He did not see that any action was called for on the part of the British Government.

Workmen's Compensation

Mr. CLYNES, in a reply to Mr. M'Kinlay on April 2nd, said he had received complaints as to several of the medical referees appointed for Lanarkshire under the Workmen's Compensation Act. The allegations had been of a general character, to the effect that the referees were biased against the workmen and their decisions unfair. These allegations had not been supported by evidence. Particulars of only three cases in which it was alleged that the workman had been unjustly treated had been submitted. While not in a position to review the decisions of referees, he had carefully examined these particulars, and could not find anything in them to sustain such a charge. Great pains were taken to appoint as referees doctors of the highest possible standing and professional qualifications; once a person was appointed to a judicial post of this kind he was entitled to expect that the Home Secretary would not countenance charges of unfairness except on clear and definite evidence of incompetence or bias. Mr. M'Kinlay further asked if Mr. Clynes would appoint a small committee to survey the decisions of the referees. Mr. CLYNES replied that such a general survey would not be justified even if practicable.

Atmosphere of House of Commons.—On a vote for expenditure on the Houses of Parliament, Miss WILKINSON asked if anything was being spent on improving the system of ventilation. The sickness rate, and even the death rate, among members of Parliament had been high in the past few months. All of them felt that when they came into the House they were entering a building where no fresh air seemed to enter. Mr. LANSBURY said that he did not understand the criticisms of the atmosphere of the House. The reports on it all disagreed with one another, and the experts that he had consulted contradicted one another. A committee was appointed recently on the subject, and it reported that such defects as existed in the ventilation were attributable to the methods of distributing the air current, and not to the quality of the air admitted, which was both chemically and bacteriologically pure. Mr. SOMERVILLE HASTINGS asked if that examination had been made when the House was sitting. Mr. LANSBURY said that all he knew was that the committee reported in 1905. In 1923 another committee made certain recommendations, the important part of which had been carried out. The House agreed to the vote.

Patent Medicines.—On March 30th Mr. PETHICK-LAWRENCE told Mr. Hastings that the cheap edition of the report of the Select Committee on Patent Medicines (1914) had been out of print for some years. There was no evidence of a substantial demand to justify a reprint. The full edition, containing the Proceedings and Minutes of Evidence, was still available.

Sweepstakes for Hospitals.—On March 31st Mr. TOOLE asked the Prime Minister if the Government could see its way to introduce legislation to enable sweepstakes similar to those in the Irish Free State to be conducted in this country to aid hospitals in need of funds. Mr. CLYNES, who replied, said that, apart from any other consideration, he had yet to learn that the hospital authorities desired such legislation.

Bethlem Royal Hospital.—On March 31st the House of Commons considered the Civil Estimates in committee. Mr. CHARLES WILLIAMS called attention to an item headed "Bethlem Royal Hospital: adaptation for Imperial War Museum." He said that that represented £50,000, and the committee was entitled to know what was being done to the hospital. Mr. LANSBURY, in reply, said that originally it was proposed to pull down the whole building, but it had now been decided that the War Museum should be transferred there. The London County Council would have to bring in a Bill to obtain powers from Parliament to alter the original Act for dealing with Bethlem Hospital.

Refuse Disposal.—Miss LAWRENCE, answering Mr. Mills on March 30th, said that it was not proposed to bring in a Bill this session dealing expressly with the dumping of refuse. The Town and Country Planning Bill recently introduced would strengthen the hands of the planning authorities in preventing or controlling the use of land for such a purpose. Local authorities might also prevent nuisance if by-laws dealing with the disposal of refuse were made and strictly enforced.

Vaccination.—In the House of Commons, on March 30th, Mr. GROVES presented a Bill to repeal the law relating to compulsory vaccination.

Contraceptive Literature.—Replying to Sir James Reynolds on April 1st, Mr. VIANT said his attention had been drawn to the fact that birth control literature was being disseminated by post, but unless the language used was indecent or obscene he had no power to prohibit the transmission of such matter in this way.

Research on Animal Diseases.—Dr. ADDISON told Sir Bolton Eyres-Monsell, on April 2nd, that a scheme for developing research into animal diseases upon a considerable scale was in an advanced state of preparation.

Notes in Brief

In Scotland 7,851 children under the age of 12 months died during 1930—an infantile death rate of 83 per 1,000.

Universities and Colleges

UNIVERSITY OF LONDON

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

Entrance Scholarships and Exhibitions

Goldsmid Entrance Scholarships (value 112 guineas each), entitling the holder to the final course of medical study, are offered for competition in July, 1931, and are open to students who are preparing for the degrees of the Universities of London, Oxford, Cambridge, Durham, or other British universities, or for the diplomas of the Royal Colleges of Physicians and Surgeons, or for the licence of the Society of Apothecaries. A Goldsmid Entrance Exhibition (value £60) entitles the holder to a reduction by £80 of the fees due for the full course of final medical study. Only candidates who are graduates in arts or science of a university of the British Empire are eligible for this award. The Filliter Entrance Scholarship in Pathology (value £52 10s.) entitles the holder to a reduction by £52 10s. of the fees due for the full course of final medical study. No two of these awards can be held simultaneously, and holders of the Bucknill Scholarship are not eligible for them. Further particulars may be had from the secretary, University College Hospital Medical School, University Street, W.C.1.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

A meeting of the Royal College of Physicians was held on March 30th.

The Right Hon. Lord Dawson of Penn, P.C., G.C.V.O., K.C.B., K.C.M.G., M.D., was elected President.

The retiring President, Sir John Rose Bradford, Bt., delivered the presidential address for the past year.

Lord Dawson was appointed to represent the College at the forthcoming centenary celebrations of the University of Leeds on June 30th and July 1st, and Dr. William Hunter was nominated to represent the College at the forthcoming Congress of the Universities of the Empire, to be held in London and Edinburgh in July.

Diplomas

The following diplomas were granted jointly with the Royal College of Surgeons:

IN TROPICAL MEDICINE AND HYGIENE.—N. J. Abbensetts, M. Akram, J. Cairns, H. G. Calwell, C. P. Campion, M. M.-D. Chughtai, G. J. Clarke, Annie E. Connan, S. Dakshinamurty, D. Ellis, M. El Huseini, H. G. Floyd, J. R. Jensen, W. P. Jones, R. Kashwal, A. Ma, T. T. Mackie, E. W. Martindell, A. Mearns, P. B. P. Mellows, Myrtle Noronha, S. Noronha, M. Sangarapillai, D. W. Semmens, S. Thambiah, R. B. Wallace, Janet Welch, Ethel M. Weir, G. F. West, W. A. Wilson.

IN OPHTHALMIC MEDICINE AND SURGERY.—S. Atta-Ullah, B. P. Danard, H. D. Dastoor, T. E. Davies, J. Foster, Dorothy Guest, J. Hill, H. Kaitz, M. Kalra, J. G. Kshatri, I. Marais, G. R. Marcano, M. S. Mehkri, H. G. Nimbalker, K. J. O'Day, V. P. Patel, F. G. Roberts, A. L. Sutherland.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

The following candidates have been admitted Licentiates in Medicine and Midwifery of the College under the conjoint scheme with the Royal College of Surgeons in Ireland: G. A. Buggle, P. T. Casey, Annie J. Dunlevy, E. F. C. Earl, M. J. Kohane, A. C. L'Estrange, J. D. S. Murray, I. M. McLachlan, J. D. H. Widdess.

Medical News

May 12th, the anniversary of Florence Nightingale's birthday, is to be celebrated this year as Red Cross Day throughout the Empire. In London the County of London branch of the British Red Cross Society will lay a wreath on the Florence Nightingale memorial in Lower Regent Street. In Hampshire the county branch is organizing a pilgrimage to Florence Nightingale's grave in the little churchyard near Embley. Other county branches throughout the country are arranging their own ways of illustrating the work they are carrying on. In London a Red Cross flag day is to be held on May 14th, and on May 16th there is to be a big parade of V.A.D. detachments at the Duke of York's headquarters, Chelsea, at which H.R.H. Princess Mary, Countess of Harewood, will present colours to the County of London branch of the society. Notifications have already been received at the headquarters of the society that Red Cross Day is to be observed widely throughout the Empire. In Canada, Australia, and South Africa preparations for its observance are now in progress.

At the next meeting of the Society of Medical Officers of Health, to be held at 1, Upper Montague Street, Russell Square, W.C., on Friday, April 17th, at 5 p.m., a discussion on the pre-school child will be opened by Dr. Ethel Cassie, chief child welfare medical officer, Birmingham, and Dr. G. C. M. M'Gonigle, M.O.H., Stockton-on-Tees.

At a meeting of the British Institute of Radiology, to be held on Thursday, April 16th, at 8.30 p.m., at 32, Welbeck Street, W., papers will be read by Mr. H. S. Souttar on the ideal distribution of radon seeds, by Mr. W. E. Schall on a two-valve transformer unit for diagnosis and therapy; by Dr. Orliansky on uniformly impressed reduced prints from contrasty negatives; and by Dr. L. A. Rowden on a technique of radiographic pelvimetry. On the morning of April 17th medical members are invited to visit the radiological department of the North Middlesex Hospital, Silver Street, Edmonton, N., at 11 o'clock.

The Standing Conference of Metropolitan Borough Tuberculosis Care Committees has arranged an exhibition and sale of handicrafts by tuberculous patients, to be held on April 22nd and 23rd, at the Carpenters' Hall, Throgmorton Avenue, E.C. The exhibition will be opened on Wednesday, April 22nd, at 3 p.m., by the Lord Mayor, accompanied by the Sheriffs.

The annual dinner of the Medical Superintendents' Society was held at the Holborn Restaurant on March 27th. Eighty-four members and guests sat down, under the chairmanship of Dr. E. W. G. Masterman. Among the visitors present were Sir Arthur Newsholme, K.C.B., Sir William Barber, Dr. Tate (medical officer of health for the county of Middlesex), and Drs. Brincker, Daley, and Fairfield, representing the headquarters medical staff of the London County Council. Sir Arthur Newsholme responded to the toast of "The Visitors," and a musical programme added to the enjoyment of a most successful evening.

The Tavistock Square Clinic for Functional Nervous Disorders announces that twenty-four lectures on psychological types and mechanisms (an introductory course of psychological medicine for the general practitioner) will be given by Dr. H. Crichton-Miller and Dr. E. Graham Howe, at the Royal Anthropological Institute, 52, Upper Bedford Place, W.C., on Thursdays, beginning April 30th. The lectures are open to the medical profession only. Fee for either series, £1 11s. 6d.; for both series, £2 2s. Tickets for the course must be obtained in advance from the honorary lecture secretary at the clinic, 51, Tavistock Square, W.C.1.

As already announced, the annual meeting of the Canadian Medical Association will be held at Vancouver from June 22nd to 26th, and a special section of military medicine is being arranged in connexion with it. Steamship and other excursions are contemplated, and those who wish to have hotel accommodation reserved should communicate, before April 30th, with Dr. W. S. Turnbull, 925, Georgia Street West, Vancouver, British Columbia.

A post-graduate course on the medical and hydrological treatment of diseases of the alimentary canal, liver, and nutrition will be held at the Hôpital Necker, under the direction of Professor Maurice Villaret, from April 20th to May 1st, followed by a visit to Vichy from May 2nd to 4th. The fee is 300 francs. Further information can be obtained from the secretary of the Paris Faculty of Medicine.

The report of the Department of Scientific and Industrial Research for the year 1929–30 has now been published (Cmd. 3789. London: H.M. Stationery Office. 3s. 6d.). Among the subjects discussed by the Advisory Council are food investigation, water pollution, atmospheric pollution, and the work of research associations.

The annual report of the Industrial Health Education Society for 1930 records the fact that, in the six years of the existence of this society, 1,600 health talks have been given to all classes of workers in England, Scotland, and Wales. So many requests were received last year for these talks that several had to be deferred until 1931. It is proposed to develop the work of the society among the large body of women workers in mills, workshops, and factories, and also among male workers unattached to trade unions. A leaflet on eye troubles has been distributed widely.

The first Bolivian Medical Congress will be held at Sucre, the capital of Bolivia, on May 25th, under the auspices of the Government.

The French Society of Ophthalmology will hold its congress in Paris on May 4th, when the principal subject for discussion will be heredity of ocular affections, introduced by Professor van Duyse of Ghent. During the congress there will be an exhibition of optical instruments.

The following German congresses will be held in May: General Medical Society for Psychotherapy at Dresden, 14th to 17th; Oto-rhino-laryngological Society at Leipzig, 21st to 23rd; Dermatological Society at Vienna, 24th and 25th; Tuberculosis Congress at Kissingen, 26th to 30th.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Alcoholism

"W. E. M." writes: In reply to the inquiry by "A. B. C." (April 4th, p. 610) for some substance which can advisedly be put into alcoholic drinks, such as whisky, to engender a distaste in an addict, I suggest 1½ ounces of paraldehyde into one bottle of whisky. If this is not effective, send the patient to a voluntary home for alcoholic addiction.

Pregnancy Records

Dr. J. L. DIGBY (Tenterfield, N.S.W.) writes: In reply to "J. J. S." in the *Journal* of December 20th, 1930 (p. 1072), I would like to inform him that the pregnancy record published by him is beaten by a patient of mine, who was delivered on February 3rd, 1929, of a healthy full-time female child. The child was breast-fed, and the mother never menstruated. On December 1st, 1929, I confined her again; another fully developed female child was born.

LETTERS, NOTES, ETC.

Treatment of Varicose Ulceration

Dr. E. GARDEN (Leyton, E.) writes: Your columns have been so much occupied lately with correspondence either eulogizing or deploring the direct application of adhesive strapping to varicose ulcers that a method described in your issue of October 4th, 1930, would seem almost to have been overlooked. The moist paste bandage treatment described by K M and C J. Cellan-Jones appealed to me because of its simplicity of application, and I have had opportunities to prove its value in different cases. I am prompted to write this letter by reason of a recent severe case of varicose ulceration where the all-important demand was a speedy return to full work. The ambulatory paste bandage technique was carried out according to the authors' instructions, and sound healing was secured in a period of just over three weeks. The patient was delighted with the freedom from pain which followed the first application, and the other noteworthy feature was the rapidity with which a considerable degree of oedema was reduced. I have no hesitation in commending the paste bandage to the busy general practitioner, for the following reasons: (1) no special skill is required in its application; (2) it allows of the evaporation of secretions and is the readiest means of relieving pain; (3) it secures healing if conscientiously applied.

Dr R W. COCKSHUT (Hendon) writes: I do not think that sufficient gratitude has been expressed by the general practitioner to Mr Dickson Wright for perfecting the elastoplast treatment of varicose ulcers. This treatment may be as old as [illegible] but I do not recollect anybody telling me about it when I was a student. I have spent many hours using [illegible] paste with absolutely no success. Mr. Dickson Wright is one of the benefactors of the twentieth century. When he thinks of the thousands of ulcers now [illegible] England he must be a happy man. May I say that I have found painting the leg with glycerin ichthyol 5 per cent. an excellent preventive of irritation and dermatitis?

Hypodermic Medication

"J. V. M." (Co. Cavan) asks us to reproduce the description of subcutaneous injection published in the *Dublin Medical Press*, March 12th, 1845, "as it would be of interest after Mr. Cathcart's quotation of Dr. Wood's description of hypodermic medication in the *Journal* of February 21st (p. 336)."

*** The report is headed "Neuralgia—Introduction of Fluid to the Nerve. By Mr. Rynd." The patient was a woman, aged 59, admitted into the Meath Hospital and County of Dublin Infirmary on May 18th, 1844, complaining of acute pain over the entire left side of the face. She had been so much in the habit of taking laudanum that latterly half a drachm, three times a day, had no effect in lulling the pain, and this was the quantity she commonly took. "She was a miserable sallow-complexioned looking creature, had been sleepless for months, and her face was furrowed with constant pain. On the 3rd of June a solution of fifteen grains of acetate of morphia, dissolved in one drachm of creosote, was introduced to the supra-orbital nerve, and along the course of the temporal, malar, and buccal nerves, by four punctures of an instrument made for the purpose. In the space of a minute all pain (except that caused by the operation, which was very slight) had ceased, and she slept better that night than she had done for months. After the interval of a week she had slight return of pain in the gums of both upper and lower jaw. The fluid was again introduced by two punctures made in the gum of each jaw, and the pain disappeared. After this the pain did not recur, and she was detained in hospital for some weeks, during which time her health improved, her sleep was restored, and she became quite a happy-looking person. She left the hospital on the 1st of August in high spirits, and promised to return if she ever felt the slightest pain again. We conclude she continues well, for we have not heard from her since." Another case, that of sciatica in a man, aged 28, treated in the same way by Mr. Rynd, was reported in the same issue of the *Dublin Medical Press*. A description of Francis Rynd's instrument appeared in the *Dublin Quarterly Journal of Medical Science*, 1861, xxxii, 13.

Peking Man

The issue of *Antiquity* for March is especially distinguished by an admirable account of the discovery of primitive man in China by Professor G. Elliot Smith, whose lectures on the subject in London and in Edinburgh have been noted in recent issues of the *Journal*. It will be recalled that Professor Elliot Smith regards the discovery of the Peking remains as marking a new epoch in human palaeontology, since they not only provide much unequivocal information concerning a third and hitherto unknown genus of early Pleistocene man, but demonstrate that the *Pithecanthropus* of Java and the *Eoanthropus* of Piltdown are not really incompatible, "with one another. "The brain-case of *Sinanthropus*," he writes, "reveals many features which are unknown either in the Ape-man of Java or in the Piltdown skull, and throws a great deal of light upon the characters of the common ancestor of the human family, from which all these genera had been derived. One of the most striking illustrations of this fact is the peculiar form of the mastoid region of the temporal bone, recalling as it does the condition found in the newborn child and in the adult anthropoid apes. For it lacks that salient character which is so distinctive of the adult human being of other genera." The article is vivaciously written, and is illustrated by a number of plates.

A Link with the Past

The widow of Fred Wood, who was for many years the resident apothecary of St. Bartholomew's Hospital, died on April 2nd at Bournemouth, within two months of completing her hundredth year. She was the eldest daughter of William Birch of Barton, and the aunt of Mr. J. Lionel Stretton of Kidderminster.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 51, 52, 53, 54, 55, 58, and 59 of our advertisement columns, and advertisements as to partnerships, assistantships and locumtenencies at pages 56 and 57.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 115.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

338 Etiology of Chorea

R. LENZ (*Wien. Arch. f. Innere Med.*, January 20th, 1931, p. 95) discusses the etiology and pathology of chorea and refers to the toxicity of nirvanol (see *Epitome*, February 21st, para. 172). He regards the streptococcal origin of infective rheumatism as definitely proved; it is a disease of adolescence, appearing about the 16th year as arthritis or chorea in 60 per cent. of all cases. Dental sepsis and tonsillitis at that age play only a subordinate part in the etiology. Rheumatic chorea is attributed to infective emboli of cardiac origin, initiating a cerebral periarteritis, followed by a round-celled exudate and, in severe cases, a choreic polioencephalitis. The arterial walls undergo degenerative changes, and the generalized infection produces cardiac dilatation, tachycardia, and albuminuria. In a fatal case of chorea in a boy, aged 15, the small ganglion cells of the neostriatum showed advanced degeneration, and in the subthalamic region a haemorrhage was found. Lenz believes that all concurrent systemic changes found in chorea are due to these generalized arterial lesions. He prescribed nirvanol in 27 cases, but it produced toxic symptoms in 41 per cent. of the patients; 19 improved, but of these 10 exhibited toxic symptoms—fever and dermatitis—while 5 had dermatitis only. Further, three patients had hyperpyrexia but no rash, though polyarthritis occurred. Two patients recovered completely without toxic symptoms. Nirvanol is cumulative in action, and the maximal approximates to the toxic dose. Lenz affirms that the proofs of definite arterial lesions of the central nervous system in chorea are: (1) degenerative changes in the small ganglion cell system of the corpus striatum, and in the cells of the hypothalamic nuclei; and (2) inflammatory vascular lesions in comparatively chronic, mild cases, or acute (polioencephalitic) cases. Nirvanol relieves irritation of the large cell systems of the corpora striata. It appears to have a specific organic action, with a narrow margin between the maximal and the toxic doses. Toxic albuminuria may occur early or late. Toxic pyrexia may subside when cerebral congestion is relieved.

339 Dengue Fever

J. S. SIMMONS, J. H. ST. JOHN, and F. H. K. REYNOLDS (*The Philippine Journ. of Sci.*, January–February, 1931, p. 1) present a comprehensive experimental study of dengue which they made in the Philippine Islands. Two important vectors of the disease are the mosquitos *Aedes aegypti* and *Aëdes albopictus*; these insects are influenced by variations in the rainfall and temperature, and dengue shows corresponding seasonal variations. The virus was not identified microscopically; in certain circumstances it may be passed through diatomaceous earth filters. In man the average incubation period was between five and six days. The onset was abrupt, with fever, headache, flushing of the face, aching of the eyes, pain in the back and extremities, and leucopenia on the first or second day after the onset. As the disease progressed, further symptoms were primary and secondary rashes, post-orbital pains and backache, pains in the limbs and joints, altered sense of taste, and adenopathy. The leucopenia was mainly due to a decrease in the lymphocytes and mature neutrophilic granulocytes. The marked cellular degeneration indicated that the leucopenia was due to a destruction of these cells; it also seemed possible that the virus might multiply within the leucocyte, causing its death. The immunity following an attack of dengue is probably completely protective in most cases. With the possible exception of complement-fixing bodies, specific antibodies were not demonstrated in the serum during and following recovery from the disease. Though results so far have been negative, it is believed that an effective prophylactic vaccine may eventually be obtained. Dengue outbreaks in lower animals are also discussed.

340 Diagnosis of Congenital Syphilis

D. NABARRO (*Brit. Journ. Vener. Dis.*, January, 1931, p. 1) discusses certain symptoms common in congenital syphilis, the non-recognition of which leads to diagnostic errors. Frequently a child is born apparently healthy, but it develops snuffles, and some weeks later a rash, which must be differentiated from the napkin rash due to irritation by urine; the latter rash is usually brighter and less extensive. Condylomata, not common in children, are rarely seen before the age of 1 year; these lesions are usually quite characteristic. Syphilitic osteo-periostitis or epiphysitis are demonstrable by systematic *x*-ray examinations. A mild hydrocephalus may be associated with inherited syphilis in early childhood. An important symptom of neurosyphilis, often overlooked, is inequality of the pupils with or without reaction to light and accommodation. Spastic paraplegia is another overlooked symptom; this may be a mono-, di-, or paraplegia. Bilateral hydarthrosis, especially of the knee, is usually of a syphilitic nature. Interstitial keratitis is the commonest symptom of late inherited syphilis. Minor degrees of Hutchinsonian teeth often occur. Nabarro emphasizes the importance of the Wassermann test in all doubtful cases, and the need of its repetition if the reaction is doubtful. He believes that mercury alone is not a reliable drug in congenital syphilis, but that it should be associated with an arsenical; as soon as the diagnosis is made he begins injections of some arsenical or bismuth preparation. In certain cases it is advisable to start with mercury for a few weeks, and then to give very small arsenical injections.

341 Erythema Nodosum and Tuberculosis

A. CEDERCREUTZ (*Finska Läkaresällskapets Handlingar*, January, 1931, p. 61) has investigated the after-histories of the patients in private or hospital practice who, before 1910, had suffered from erythema nodosum or multiform exudative erythema. There were 63 cases of erythema nodosum, only 10 of the patients being males; of 78 patients with multiform exudative erythema 40 were males. Both these skin diseases occurred most frequently between the ages of 20 and 40, and they were most common in the colder months of the year. Cedercreutz succeeded in tracing 26 of the 63 patients who had had erythema nodosum, and among these 26 there were nine deaths. Only in two instances was pulmonary tuberculosis the cause of death; it had proved fatal from eleven to fifteen years after the outbreak of the erythema nodosum. Of the 78 cases of multiform exudative erythema 36 were traced, and as many as 20 of these patients were found to have died, but only in five instances was the cause of death notified as being pulmonary tuberculosis. This investigation suggests that patients who have undergone one or other of these two skin diseases are not as a class peculiarly susceptible to fatal pulmonary tuberculosis.

342 Post-vaccinal Encephalitis and Generalized Vaccinia

M. WEICHSEL (*Monatsschr. f. Kinderheilk.*, January 30th, 1931) records the case of a male infant, aged 17 months, who nineteen days after vaccination which had run a normal course developed severe cerebral symptoms and convulsions, followed by left spastic hemiplegia. Varicella and epidemic encephalitis could be excluded, and the cause of the generalization of the vaccinia was obscure. Inoculation of a rabbit's testicle with the cerebro-spinal fluid, and of its cornea with the contents of a vesicle, had no result. The long incubation period of nineteen days was remarkable, but several cases in which it was even longer have been observed in both England and Holland.

343 Pancreatitis complicating Mumps

Pancreatitis is an infrequent complication of mumps; at the same time it presents a characteristic symptom-complex. M. B. BRAHDY and I. H. SCHEFFER (*Amer. Journ. Med. Sci.*, February, 1931, p. 255) report 13 cases in 252 patients during slightly over a year. The disease may occur in either sex at any age. In this series the age extremes were 6 and 30 years. The onset is sudden between the fifth and eleventh days of the illness, with nausea, anorexia, and fever. The temperature rises in a day or two to 103° or 104° F. in moderately severe cases, and returns to normal in three to five days. As a rule the pulse is relatively slow. Patients complain of malaise, nausea, headache, and abdominal pain; they usually vomit. In the present cases the pain and tenderness were always referred to the upper part of the abdomen. Most of the patients were constipated; diarrhoea, reported by other observers, did not occur. There was no glycosuria. Pancreatitis may be confused with other complications of mumps, such as meningitis, aural complications, and oöphoritis in females. Only two necropsies have been recorded in the literature. The pathological pancreatic changes reported by Lemoine and Lapasset are described; these are comparable to those found by Wollstein in the parotid glands of monkeys experimentally inoculated with mumps. Reports of three illustrative cases are given.

344 The Intradermal Tuberculin Reaction

A. MONCRIEFF (*Quart. Journ. Med.*, January, 1931, p. 153) discusses the value of the intradermal tuberculin test, and reports a series of 206 children suffering from various illnesses who were submitted to it. He concludes that in pneumonia a positive reaction by no means necessitates a gloomy prognosis, and a negative one does not exclude tuberculosis if the usual dose of 0.1 mg. is employed. In two cases of acute bronchitis positive results were obtained, but the conditions nevertheless proved subsequently to be non-tuberculous. A general survey of the 118 cases leads Moncrieff to give a warning that the instances where the Mantoux intradermal tuberculin test is helpful are limited. The value of a negative reaction is reduced by four possibilities—namely, the brand of tuberculin used may not be potent; the injection may have been made subcutaneously instead of intradermally; the patient may be one of the small group where bovine tuberculin is necessary to obtain a positive result; and the patient may be in such an acute state of tuberculosis that a negative result is obtained with ordinary doses of tuberculin. A positive reaction implies at the most that there has been some previous infection with tuberculosis, but the test must be carefully controlled. Even at an early age a positive reaction should not be allowed to establish a diagnosis, but should merely be one of the factors in reaching it.

Surgery

345 Cerebellar Astrocytomas

H. CUSHING (*Surg., Gynecol. and Obstet.*, February, 1931, p. 129) in a critical review of 76 cases records experiences with the cerebellar astrocytomas, gliomatous tumours having a neoplastic basis composed of highly differentiated neuroglial cells known as astrocytes. The symptoms usually date from childhood, and include periodical morning headache and vomiting. Secondary hydrocephalus invariably results from their mid-cerebellar situation, leading to choked disc so insidious in origin that impaired vision may be the first symptom noticed; the tumour may attain considerable size before any cerebellar signs of instability become manifest. Headache is more often frontal than suboccipital, and the symptoms depend more upon the variability of tension of the secondary hydrocephalus than upon purely [illegible] factors. The physical signs of cerebellar involvement may be inconspicuous; nystagmus when I was a student the hydrocephalus is often out of all proportion to the determinable cerebellar signs. Pain mainly affects the lower extremities, often some suboccipital tenderness, tilting of the head is not noticeable owing to the usual mediate position of the growth. The tumours may be either compact or largely cystic, in which latter condition recurrence of symptoms after operation is inevitable unless the mural nodule of tumour is identified and removed. The tumours may be exposed on the surface or be wholly concealed; if buried, they can be exposed and removed under local anaesthesia by means of a vertical incision through the vermis. The astrocytomas are almost equally divided between the sexes, and, though probably congenital in origin, a history of pre-symptomatic trauma is given in a large proportion of the cases.

346 Hydatid Cysts of the Lung

J. ABADIE (*Bull. et Mém. Soc. Nat. de Chir.*, February 7th, 1931, p. 124) reports ten cases of hydatid cysts of the lung which were treated surgically. The disease, which is rare in France, occurs frequently in Northern Africa. Although statistics generally show that hydatid cysts are most common in men, and in the right lung, it was found that in the ten cases under review the incidence was equal in the two sexes and occurred as often in the left lung as in the right. Five of the patients were under the age of 20, the two youngest being only 9. Typical vomiting and expectoration are the most characteristic symptoms, but diagnosis is confirmed by the use of radiography, which discloses the site of the cyst. Treatment depends on the position and condition of the cyst; if it is central and not infected immediate operation is not advisable, whereas if it is infected and in a central position operation must be performed immediately in spite of the risk. If the cyst is peripheral but not infected an operation should only be undertaken after careful deliberation. In cases where an operation discloses adhesions, these should be left, the cyst being opened and the pocket removed. If the cyst is suppurative ample drainage must be left, and in any case it is advisable to leave a small transitory drain which can be removed if all goes well. In cases where no adhesions are present a two-stage operation is advocated. One patient who was intensely cyanosed was relieved immediately by the attachment of the pleural drain to a tube which was sunk in a jug of water placed near the ground. There were no cases of post-operative bronchial fistula, and all ten patients made a good recovery.

347 Renal Sympatheticotonus and Sympathectomy

S. H. HARRIS and R. G. S. HARRIS (*Canadian Med. Assoc. Journ.*, February, 1931, p. 235) believe that renal sympatheticotonus is a definite clinical and pathological entity. The possibility of a neuropathic basis was considered in many patients with renal pain in whom urological examination revealed little or no abnormality. Accordingly, a denervation of the kidney (renal sympathectomy) was performed on one patient; the results were so satisfactory that the operation has since been performed in 28 cases with equally gratifying effects. The nerve supply of the kidney and the operation are described. The latter, though extremely tedious and necessitating painstaking care, has been found to relieve the pain completely and permanently. The following syndrome definitely indicates renal sympatheticotonus: positive pain reproduction test on cystoscopic examination; positive pyeloscopic and pyelographic findings; delayed emptying time of the renal pelvis and calyces, or possibly of a single calyx; recurrence of pain after its temporary relief by eserine; evidence of generalized sympatheticotonus, which may be most marked on the side of the lesion; negative urinary findings on microscopical and cultural examinations; proved absence of organic ureteral stricture. The indications for sympathectomy fall broadly into three groups: irregular and incomplete contractions of the calyces and pelvis, so that the peristaltic impulse either does not reach or does not pass beyond the uretero-pelvic junction; marked slowing down with irregularity and increased power of the contractions, associated generally with dilatation of the pelvis and clubbing of the calyces; and dilatation and immobility of a single calyx. Delayed emptying occurs in all the groups.

348 **Actinomycosis of the Abdomen**

L. P. GOOD (*Arch. of Surg.*, February, 1931, p. 307) states that out of 62 cases of abdominal actinomycosis the primary lesion occurred in the ileo-caecal region in 77.5 per cent. It was not found possible to substantiate or contradict the theory that the organism is carried into the tissue by some foreign material such as straw, nor was evidence obtained that an injury, such as might be caused by straw, provided a point of entry for the organism already present in the mouth; 12 of the 62 patients were farmers. Symptoms of abdominal actinomycosis may be chronic, when the presence of a mass in the right lower abdominal quadrant is usually the first indication; in the acute form there is pyrexia with pain and tenderness. A diagnosis of appendicitis is generally made, and operation frequently discloses an appendix abscess, which is drained. Several weeks after the operation, however, symptoms recur and another abscess is found either in the incision or in some other part of the right flank or renal region, which, after drainage, leaves a sinus. The fungus makes its way by direct growth along the fascia, peritoneum, and muscles until a new abscess and sinus is formed. Later the blood stream may become infected and metastatic abscesses develop in any part of the body. If the lesion is primary in the ileo-caecal region the lung is affected in 20 per cent. of cases, but if the actinomycosis originates in the upper part of the abdomen the lung is affected in 50 per cent. Treatment, which must be surgical, consists of incising and draining the abscesses, curetting the sinuses, and establishing perfect drainage, in conjunction with medical treatment and *x*-ray or radium therapy. Massive doses of a saturated solution of potassium iodide have given good results, but the prognosis is poor. Of the 62 cases reported, 29 patients died, 7 did not improve, and 6 had improved; the disease had apparently been arrested in 8 cases, and 12 cases could not be traced.

349 **Acute Necrosis of the Pancreas**

M. MARTENS (*Med. Klinik*, January 30th, 1931, p. 155) believes that acute pancreatic necrosis is more common than was formerly supposed. With the necrosis of the gland, in whole or in part, are associated haemorrhage, inflammation and fat necrosis, and self-digestion of the pancreatic tissue by its own secretion rendered prematurely active within itself. Possible predisposing factors include disease of the gall-bladder or bile ducts (especially in pregnancy and labour), gastric or duodenal ulcers, threadworm in the pancreatic duct, pancreatic stone, and excesses in eating and drinking; stout elderly women are frequent subjects. Among external causes are violence, accidental trauma during operation, and the passage of a sound up the ducts of Santorini or Wirsung. The symptoms are characteristic—namely, sudden onset of steady, excruciating pain in the upper part of the abdomen, radiating to the back and occasionally to the left shoulder; the abdomen is soft, and a tumour lying in the position of the pancreas may be located. Tenderness is found, not only towards the left. Vomiting is usual; it is not faecal, but the vomit contains blood, at first altered, and later fresh; this associated with anuria and cyanosis is a bad sign. The pulse, temperature, and degree of leucocytosis are variable, but collapse is common. There is no passage of faeces or flatus, but the bowel is not palpable. An *x*-ray examination gives a characteristic picture. Rise of diastase in the urine to over 64 units is almost diagnostic, the blood sugar is high. The differential diagnosis must be made from a perforating peptic ulcer, ileus, appendicitis, embolism, or thrombosis of mesenteric vessels; diseases of the gall-bladder and ducts are frequently concurrent. The most satisfactory treatment is early and very careful operation. The after-treatment is difficult; insulin may be necessary. Complications and even recurrences may ensue. As prophylaxis the author suggests early treatment of the predisposing condition, and examination of the pancreas in gall-bladder operations; an estimation of the diastasic content of the urine is an important precautionary measure in doubtful cases.

Therapeutics

350 **Sodium Iodide in Nasal Infections**

A. LEWY (*Arch. of Otolaryngol.*, January, 1931, p. 97) reports successful results in hypertrophic rhinitis and the early stages of acute coryza from the hypodermic injection of a 3 per cent. solution of sodium iodide. After the solution has been prepared and sterilized, it is allowed to stand for several days in a white glass-stoppered bottle until free iodine appears, when 1 c.cm. of the solution is injected. There is sometimes a temporary exacerbation of the symptoms, and five days are allowed to elapse before the next injection. After some weeks too much free iodine is present, and the solution must be discarded, since its use is attended by excessive pain. In some cases the solution was diluted ten times, with a view to minimizing the local reaction, but the results were more doubtful. Several patients were relieved in this way from chronic rhinitis after other treatment such as local applications and allergic stimulation had failed. The author commends for further trial this method, which was originally suggested by H. Sternberg and M. Sugar.

351 **Rectal Injections of Hypertonic Saline Solution**

R. SOUPAULT (*Paris Méd.*, February 14th, 1931, p. 154) has found intravenous injections of hypertonic sodium chloride solution most valuable in relieving post-operative and other grave forms of intestinal obstruction. One patient, fifteen days after appendicectomy for perforation and purulent peritonitis, developed alarming symptoms of obstruction. These were relieved rapidly by the intravenous injection of hypertonic saline solution. Soupault could not determine whether the success was due to its effect on the general toxic condition, or whether it had a more direct action on the intestinal musculature. In any case, the toxic symptoms of vomiting and tachycardia subsided, and the patient passed much flatus. On the hypothesis that the hypertonic saline solution might have a specific action on peristalsis, Soupault decided to try the rectal injection of hypertonic solution in the case of an obese woman suffering from paralytic ileus of three days' duration following cholecystectomy. The patient was greatly distressed by abdominal distension and consequent dyspnoea, so 50 c.cm. of a 15 per cent. sodium chloride solution (containing 75 grams of the salt) was injected. Within a few minutes a great volume of flatus was passed, followed by copious evacuations during the next twenty-four hours. Soupault had a similar success in a woman operated upon for a pelvic peritonitis following ruptured pyosalpinx. Another patient was a cachetic old man who had repeated attacks of partial obstruction due to some chronic inflammatory adhesions. Small injections of hypertonic saline solution invariably relieved him. Soupault now employs this method as a routine procedure in cases of threatened obstruction, and also in cases of localized pelvic peritonitis, acute pericholecystitis, and subacute appendicitis. He considers that it is indicated in all obscure subacute abdominal cases which do not need an operation. The technique is very simple: 100 c.cm. of 10 per cent. hypertonic sodium chloride solution is injected into the rectum through a small catheter, sterilization of the solution being unnecessary.

352 **Treatment of Addison's Disease**

L. G. ROWNTREE and others (*Journ. Amer. Med. Assoc.*, January 24th, 1931, p. 231) record the treatment of a series of cases of Addison's disease with a hormone derived from the cortex of the suprarenal gland, and lay down the following principles of therapy in this disease. In addition to the most assiduous attention to the details of general care, dieting, and resting, three forms of treatment are of importance. The dehydration which occurs during the crises should be countered by the administration of a solution containing dextrose (10 per cent.) and sodium chloride (1 per cent.), the authors consider that this is unquestionably the best method to adopt in the absence of supplies of the hormone. The second form of treatment

is the "Muirhead" method of pushing adrenaline to the point of intolerance by subcutaneous injections and maximum doses by the mouth and rectum; this is effective in some cases, but apparently valueless in others. The third line of treatment is the daily intravenous injection of 10 to 20 c.cm. of the cortical hormone in divided doses, the immediate results of which in a crisis are most gratifying. Such injections prove effective as a rule within forty-eight to seventy-two hours, but it remains to be shown whether such a combination of various lines of treatment will sustain life and health for a number of years. This is not the case with the Muirhead method alone, but its association with the cortical hormone seemed much more hopeful. This hormone is said not to be yet available commercially, but the authors state that the problem of its preparation is engaging the attention of the council on pharmacy and chemistry of the American Medical Association.

353 Massive Doses of Sodium Salicylate in Acute Rheumatism

CASSAËT, GRÉ, and J. LÉVY (*Journ. de Méd. de Bordeaux*, February 20th, 1931, p. 138) describe two cases in which large doses of sodium salicylate proved very efficacious. A previously healthy woman, aged 38, had a sudden attack of pain in the right hypochondrium, with frequent dry cough. Basal pleurisy was found, and two days later a pericardial friction sound appeared. After eight days transient arthralgias occurred. Daily doses of 185 grains of sodium salicylate were given, and all symptoms disappeared in two days, but a mitral systolic bruit appeared subsequently and became permanent. Notable features in this case are the unusually late incidence of a first attack of acute rheumatism; the occurrence of pleurisy and pericarditis before arthritis; and the failure of large doses of sodium salicylate to prevent endocarditis. The second patient, a woman aged 49, had had acute articular rheumatism for two months, and had been taking more than 2 drachms of sodium salicylate daily. She had generalized arthritis, pleurisy, and dry pericarditis, and was very ill, emaciated, and anaemic. She was given by the mouth 185 grains of sodium salicylate each day in 35 ounces of alkaline water, together with intravenous injections twice a day of 15 grains of this salt in 5½ drachms of glucose solution. The pyrexia subsided, and became normal on the third day. The treatment was continued for twelve days; the intravenous injections were then discontinued and 216 grains of sodium salicylate were given daily by the mouth, but two days later the temperature returned to 102.6° F. The oral administration was stopped, and an intravenous dose of 31 grains of sodium salicylate was given; the temperature fell and the patient remained afebrile until discharge. The pleurisy disappeared, but a mitral lesion developed. The authors conclude that in refractory cases of acute rheumatism the intravenous administration of sodium salicylate is indicated.

354 Calcium and Parathyroid in Chronic Ulcerative Colitis

B. HASKELL and A. CANTAROW (*Amer. Journ. Med. Sci.*, February, 1931, p. 180) report a series of cases of ulcerative colitis in which prompt improvement followed the administration of calcium lactate or gluconate by the mouth, associated with intramuscular injections of parathyroid extract. Eleven out of thirteen patients became clinically well in from four to eight weeks, and remained well for periods up to two years, during which observation was continued. The mucous membrane of the lower part of the bowel regained its normal appearance in eight. In two instances there was a slight and only temporary relapse. The authors state that experimental calcium studies in one group of patients suffering from mucous colitis, and in another group with ulcerative colitis, suggest that the ulcerative lesions are not infrequently secondary to long-standing mucous colitis. The treatment included a cellulose-free non-irritating dietary, the use of belladonna and kaolin, and doses of 20 to 30 grains of ammonium chloride, which, by intensifying the hydrogen-ion concentration of the tissues, enhanced the availability or utilization of the tissue calcium. The average adult dose of the parathyroid extract was 20 to 30 units, according to the body weight. The authors' observations indicated that it resulted in an increase in the availability and utilization of the calcium, tending also to restore a normal ratio of diffusible to non-diffusible calcium. The lactate or gluconate of this metal was administered orally in doses of 30 grains or 60 grains respectively, three or four times daily, and between three and four hours after meals. Another benefit of this treatment was the diminution of colonic spasm, even when high doses of belladonna had previously proved ineffective. The authors discuss the way in which this combined treatment acts upon the diseased tissues, and recommends its more extensive adoption.

355 Percutaneous Diphtheria Immunization

A. F. ABT and B. F. FEINGOLD (*Amer. Journ. Dis. Child.*, January, 1931, p. 8) since July, 1929, have used Loewenstein's percutaneous method for producing an active immunity against diphtheria in 62 Schick-positive children aged from 11 months to 17 years. The material used was an ointment containing not only diphtheria toxoid, but also an unfiltered culture of dead diphtheria bacilli. Three rubbings were given at weekly intervals, the back, chest, abdomen, or arms being used as the site for them. In 44 of the 62 children (70.9 per cent.) a negative Schick reaction followed the last rubbing in periods varying from 2½ to 7 months. The authors maintain that the percutaneous method produces active immunity in as large a percentage of cases as is induced by the other methods now in use, and possesses the following advantages: (1) it avoids the dangers which may be produced by introducing a foreign protein directly into the lymphatic circulation; (2) it eliminates the danger of liberating free toxin in the system; (3) it avoids the occurrence of constitutional reactions; and (4) it does not sensitize the child to other serums. A. H. KEGEL and B. M. GASUL (ibid., p. 44) applied the percutaneous method in 47 Schick-positive children, aged from 12 months to 10 years, at an infant welfare station at Chicago, three inunctions being given with ten-day intervals between them. Six weeks after the last inunction a control Schick test was performed, and 26, or 53.3 per cent., gave a negative reaction. No local or general reactions were observed.

Anaesthetics

356 Indications for Spinal Anaesthesia

Reviewing 500 cases of spinal anaesthesia induced during the last three years, J. PARRY (*Canadian Med. Assoc. Journ.*, January, 1931, p. 64) concludes that nearly all cases in which the operative field lies below the diaphragm are suitable for this type of anaesthetic. Operations above this level are at present excluded, though the author has performed double amputation of the breasts in one case, in addition to cholecystectomy, without any difficulty. Vasomotor depression constitutes the chief risk in spinal anaesthesia, and, consequently, the lower the segmental nerve block is established, the safer the case should be. Commenting on his results, Parry remarks that he has found 1 c.cm. of spinocain very useful in the disagreeable procedure of cystoscopic examinations in male patients. Contraindications to spinal anaesthesia include a profound state of shock, or severe haemorrhage with low blood pressure, but in any such case it is questionable whether any operation with any type of anaesthetic is justified before suitable pre-operative treatment has been administered. Other contraindications are: ankylosis of the spine, rendering spinal puncture impossible; infections of the back over the site of puncture, making meningitis a conceivable contingency; and disease of the spinal cord, where, in the event of paralysis supervening, the spinal anaesthesia might be blamed. The chief risk during spinal anaesthesia is cerebral anaemia, due to paralysis of the vasomotor fibres that leave the cord between the

second dorsal and third lumbar segments. This may be prevented or corrected by the administration of ephedrine or of a slowly diffusible novocain solution, or by adopting the Trendelenburg position. The author emphasizes the importance of careful observation of the patient during the onset of the anaesthesia, which in some cases takes twenty-five minutes and in others only four. The blood pressure should be recorded every three or four minutes, especially during the first half-hour, and arrangements should be made in advance for giving intravenous injections promptly should they be required.

357 Ethyl Chloride as a General Anaesthetic for Children

Although ethyl chloride (without admixture of other anaesthetics) has been used as a general anaesthetic for more than thirty years, H. SCHAEFER (*Schmerz Narkose-Anaesthesie*, December, 1930, p. 330) finds a great divergence of opinion regarding its safety that requires careful investigation. Ethyl chloride has been used very largely in brief operations and was regarded as a safe general anaesthetic, but a death occurred in 1902. Schaefer classifies all published cases as uncomplicated and complicated. In some uncomplicated cases anaesthesia was prolonged for 20 to 50 minutes. Rose has recorded 15,000 successful cases in children and adolescents up to the age of 18. Schaefer considers that ethyl chloride is indicated chiefly in operations on the nose, throat, and ear, and mentions that two authors reported 500 successful tonsillotomies. McCardie described the case of a boy, aged 11, who after five minutes of ethyl chloride anaesthesia vomited for thirty hours; he vomited for a similar period after chloroform. Seiffert described two cases in children about 2 years old. After the administration of 25 drops of ethyl chloride in a closed ether mask, apnoea with alarming symptoms of collapse occurred, but both recovered with artificial respiration, heart massage, and the administration of oxygen and camphor. In another case of collapse an intracardial adrenaline injection was successful. Hayward has recorded severe collapse, asphyxia, and cyanosis; he has discarded ethyl chloride as a general anaesthetic. Schaefer has collected nine fatal cases, and classifies the causes of these fatalities as (1) primary heart failure; (2) irritation of the olfactory and fifth nerves; (3) hypopiesis and sudden cardiac paralysis; (4) respiratory paralysis; (5) toxic action on the heart; and (6) psychic shock. He concludes that, whatever theory is accepted, it is evident that the use of ethyl chloride is not free from danger.

358 Pernocton

B. FRIEDLAENDER (*Anesthesia and Analgesia*, January–February, 1931, p. 26) records 735 cases in which pernocton was used as an anaesthetic without a single fatality. This drug (the sodium salt of the secondary butyl-β-bromallyl-barbituric acid) combines the advantages necessary in anaesthesia of possessing a long side-chain and a halogen replacement of the hydrogen atom without the disadvantages associated with some similar compounds—namely, insolubility and toxicity. It produces a state closely related psychologically to natural sleep, but the patient is impervious to external stimuli. It completely eliminates the emotional disturbances which may be so detrimental in inhalation anaesthetics. Pernocton should be administered in a dosage relative to the body weight; the average dose is 1 c.cm. per 12.5 kilos of weight. It should be given very slowly—1 c.cm. every one to two minutes. The dose may be diminished if psychological preparation is provided, and should never be large enough to abolish the reflexes. Pernocton may be used effectively as the sole anaesthetic for painful examinations, minor operations, and many obstetrical procedures. In major operations it should be used as a deep hypnotic for induction, and be associated with a small amount of ether. Friedlaender claims that pernocton is an ideal anaesthetic, since it combines efficacy and the production of benign psychic conditions with a minimum of toxicity and psychological disturbance.

Obstetrics and Gynaecology

359 Chronic Cystic Mastitis

C. SEMB (*Nordisk Medicinsk Tidskrift*, February 7th, 1931, p. 81) of the Ullevaal Hospital in Oslo discusses the pathology of chronic cystic mastitis and the divergent opinions as to this condition being a new growth, an inflammatory reaction, a degenerative process, or a developmental anomaly. He finds the average age of patients suffering from fibro-adenomatosis simplex to be about 33 years, and of those with fibro-adenomatosis cystica to be about 44 years, so that if the one is a later stage of the other the change takes on an average about eleven years. But fibro-adenomatosis simplex may remain as such or even disappear spontaneously. In a series of about 600 tumours of the breast, Semb found fibro-adenomatosis as a disease *sui generis* in just over 23 per cent., about one-third of these cases belonging to the class fibro-adenomatosis simplex, and about two-thirds being cases of fibro-adenomatosis cystica. He regards this condition as precancerous, and while he found malignant disease in only about 2 per cent. of his cases of fibro-adenomatosis simplex, it occurred in about 24 per cent. of patients suffering from fibro-adenomatosis cystica. Fibro-adenomatosis was most common among married nulliparae, whereas it was practically non-existent among multiparae. Of all his 600 cases of tumours of the breast, a bare 50 per cent. were malignant, a bare 30 per cent. were benign, and the remainder represented transitional forms. As for the treatment of fibro-adenomatosis simplex in young women, he recommends conservative methods (though he states earlier in his paper that no effective and reliable conservative treatment exists at present) or a limited operation, the patient being subsequently kept under observation. Fibro-adenomatosis cystica between the ages of 20 and 30 should also be an indication for conservative treatment, and amputation of the breast is only indicated in exceptional circumstances. But after the age of 35 or 40 the danger of cancer is so great that amputation should usually be performed.

360 Pyelonephritis in Pregnancy

D. K. ROSE and P. R. ROLLINS (*Journ. Amer. Med. Assoc.*, January 24th, 1931, p. 235) discuss the prevention and treatment of pyelonephritis in pregnancy, recording the conclusions reached after they had undertaken a series of cystometric investigations, of which details are given. They found that the pyelonephritis of infancy might be continued with markedly attenuated organisms throughout life, exacerbations occurring subsequently in consequence of the trauma and urinary retention incidental to pregnancy and labour. During pregnancy urinary retention might be caused by such factors as myomas, pelvic adhesions, cystocele, uterine abnormalities, and changes in the vesical and ureteral walls, while after labour there might ensue a special type of spasticity of the bladder wall. The authors state that the cystometer differentiates two types of neurogenic post-partum urinary retention, one being due to pressure of the child's head in the second stage of labour, and the other being of a reflex nature associated with dilatation and trauma of the outlet. In the first type, bladder drainage will cause a cystitis, but will prevent pyelonephritis, diminish moderate forms of ureteral stasis, and lessen the danger of infection or reinfection of the ureter from the bladder. They add that one useful preventive measure is the termination of the second stage of labour when it has lasted two or three hours, and when the greatest diameter of the head is within the pelvis. The employment of forceps and of morphine-scopolamine analgesia seems to exert no direct influence on urinary retention. The cystometer is an instrument which measures resistance of the bladder wall under constant filling conditions, and differentiates the myogenic and neurogenic factors in retention. The authors define the bladder sensations of "temperature," "slight pressure," "first desire to void," "fullness," "pain,"

and the "severe pain" of over-distension, basing their conclusions on the points of filling and pressure at which the various sensations occur, and their relation to each other.

361 Pregnancy and Labour in the Elderly Primipara

J. K. QUIGLEY (*Amer. Journ. Obstet. and Gynecol.*, February, 1931, p. 235) thinks the risks attending a first pregnancy and labour after the age of 30 have been much overestimated, and he does not consider that there need be any special difference in the obstetrical treatment. He reports a series of 234 private and 70 ward cases which (1) did not show a higher percentage than normal of twin pregnancies—1 to 101; (2) did not produce larger infants than the normal, the average weight being 7½ lb.; (3) did not give a higher incidence of abortions or premature labours; (4) did not disclose more fibromyomas than in multiparae of the same ages; and (5) did not result in a higher foetal mortality than the general average. Dry labours, while being frequent, were shorter than those in which the membranes ruptured earlier. Quigley found, moreover, that the duration of labour was always appreciably shorter in such elderly primparae, but there was a slight increase in the toxaemia of pregnancy. There were more cases of funnel pelves, but only a slight rise in the number of unfavourable presentations and positions. Caesarean section was required rather more often. In the small group of cases of first-stage dystocia, in which long labour does not dilate the cervix, primary inertia seemed to be mainly concerned, and cervical rigidity much less often. The dystocia in the author's series ensued usually after a satisfactory short first stage, a delay in the second stage being caused by inertia generally, but sometimes by a rigid pelvic floor. This explains, he remarks, the frequent resort to low or mid-low forceps extractions, the results as far as foetal mortality or condition of the pelvic floor were concerned being good. Lactation was, however, seldom satisfactory in elderly primiparae.

Pathology

362 Acute Nephritis produced by a Pneumococcal Autolysate

Many investigators have endeavoured to produce nephritis in animals by artificial bacterial infection or by the injection of bacterial products; their results have hitherto been negative. S. S. BLACKMAN, J. H. BROWN, and G. RAKE (*Bull. Johns Hopkins Hosp.*, February, 1931, p. 74) now report the successful production in rabbits of a characteristic acute and subacute nephritis by means of an absolutely sterile autolysate prepared from Type I pneumococcus, and also by means of intradermal infection with virulent strains of pneumococci. The toxin was shown to exert its action on the glomerular capillaries, as was evidenced by the appearance of hyaline and fibrin thrombi, and the presence of blood and fibrin in the tubules; it gave rise to injury and necrosis of the epithelium of the tubules and glomeruli. In certain cases the renal damage was associated with marked oedema of the tissues and with ascites. In man, mild acute and subacute nephritis, often unrecognized clinically, can be demonstrated in 40 to 50 per cent. of patients dying from pneumococcal infections; the renal lesions revealed closely resemble those produced in rabbits by the present authors.

363 Clinical Chemistry of the Skin

E. UEHLEIN (*Munch. med. Woch.*, January 16th, 1931, p. 89) states that the micro-chemical examination of freshly removed skin offers new possibilities for study of its physiology and pathology. The normal content of chlorides, non-protein nitrogen, sugar, uric acid, etc., is markedly different from that of the blood. The water content of the skin is high in infancy and old age, and also in obesity, scleroderma, ichthyosis, and eczema. In the last-mentioned disease the water content is high even in apparently healthy areas of the skin, whereas in inflammatory conditions such as erysipelas normal values are obtained except in the affected part. Pemphigus and dermatitis herpetiformis are characterized by an abnormal retention of chlorides in the skin. In some of the cases the actual chloride value is normal, but it invariably rises to a pathological figure after the intake of chloride. The skin is shown to be an important reservoir for sugar, nitrogen, chlorides, and water. In many cases associated with pruritus an increased non-protein nitrogen was found in the skin, even though there was no nephritis, and in some the itching appeared to be related to the uric acid fraction. Occasionally the symptom was relieved by atophan administration. It is interesting to note, however, that a prolonged protein-free diet leads to an actual increase of uric acid in the skin. Urbach believes that examination of the skin may shed new light on certain metabolic problems which have so far only been studied by chemical investigations of the blood and urine.

364 Infection due to Aberrant Paratyphoid Bacilli

M. MONNEROT-DUMAINE (*Thèse de Paris*, 1930, No. 497) applies the term "aberrant paratyphoid group" to bacilli capable of producing typhoid infections or gastro-enteritis in man, and possessing all the general characters of Schottmüller's paratyphoid B bacillus, but differing from it in their serological properties and in some of their cultural features. A large number of microbic varieties have been defined in this group, including Gaertner's bacillus, *B. aertrycke*, *B. breslau*, the Newport bacillus, the bacilli of hog cholera which are occasionally pathogenic for man—namely, the suipestifer type, the Voldagsen type, and the Kunzendorf type, which correspond to the German group of paratyphoid C bacilli, the paratyphoid C bacillus isolated by Hirschfeld in Serbia, the paratyphoid N bacilli of the G type of Russian authors, the paratyphoid bacilli of the Japanese Sasaki type, and lastly, the very rare strains which are more closely related to paratyphoid A than to paratyphoid B. Hirschfeld's paratyphoid C bacillus is important owing to its bacteriological individuality and its pathogenic role. It gives rise to septicaemic syndromes of the typhoid type, or infections without any localization or visceral forms such as broncho-pneumonia, endocarditis, and possibly jaundice and collections of pus. It is probable that aberrant paratyphoid septicaemic infections would be found to be less uncommon if all the paratyphoid bacilli isolated from the blood were submitted to agglutination tests.

365 The Blood Sugar Content in Later Life

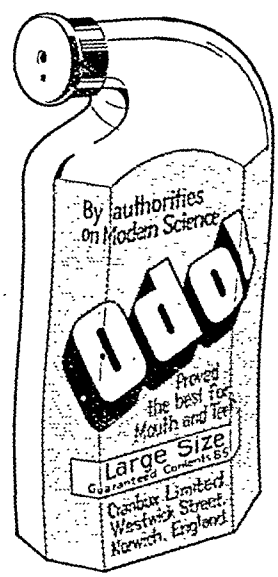
F. W. MARSHALL (*Quart. Journ. Med.*, January, 1931, p. 257) records investigations upon the sugar content of the blood in 50 men, ranging in age from 65 to 94. After an examination of the cardio-vascular system, including the blood pressure, and of the respiratory and alimentary systems, the blood sugar was estimated by MacLean's method, and the glucose-tolerance test was performed as follows. No food was allowed after breakfast at 7 a.m. until after the completion of the test, and, following an estimation of the blood sugar at 2 p.m., the urine was tested for sugar and acetone, and 50 grams of powdered glucose in 200–300 c.cm. of water were given. During the following 2½ hours half-hourly estimations of the blood sugar were made, and the urine was tested for sugar and acetone at the end of the first, second, and fourth hours. A positive reaction for acetone never occurred. It was found that five types of glucose-tolerance curves occur in healthy old persons. The "lag" type of curve was found in 25 per cent. of healthy cases; this is probably a higher incidence than in the normal adult. In the group of unhealthy cases the same five types were noted, but their incidence was altered, and the diabetic type preponderated, being found in 50 per cent. The author concludes that the majority of diseases, particularly chronic bronchitis, occurring in old age have a deleterious effect upon sugar tolerance. There did not appear to be any relation between the blood pressure, the blood sugar content, and the renal threshold; the last of these in healthy old age was found to be generally raised, and in the neighbourhood of 0.2 per cent. The presence of a septic focus produced a diminution of sugar tolerance, though dental sepsis exerted but little influence on the curve.

AN EFFICIENT ORAL ANTISEPTIC NEED NOT BE DISAGREEABLE TO THE TASTE

Too often the use of an oral antiseptic is associated in the patient's mind with disagreeable taste. That such an antiseptic need lack nothing in efficacy whilst being pleasant in taste is most forcibly proved in the instance of Odol Mouthwash.

Experiments and the experiences of medical men in the past with Odol have proved it to be a most efficient bactericide. In addition, it is absolutely harmless and cannot in any way injure the most delicate mucous membrane of the mouth.

In prescribing Odol Mouthwash doctors will obtain the desired results in a way most pleasant to the patient.



CRANBUX LIMITED
NORWICH, ENGLAND

Samples and literature will be gladly sent to members of the Medical Profession on request.

Valentine's Meat-Juice

In the **Treatment** of **Weak Babies**, in the **Gastric** and **Enteric Troubles** of **Infants** and in the **Wasting** and **Febrile Diseases** of **Children**, the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Sustain** and **Strengthen** has been **Demonstrated** in

Hospitals for Children.

The quickness and power with which **Valentine's Meat-Juice** acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for Clinical Reports.

For sale by European and American Chemists and Druggists.

Alimentary Toxæmia and Neurasthenia

NEURASTHENIA is no doubt a comprehensive term which includes several affections of different ætiology

In many of the cases alimentary toxæmia plays a considerable part; the digestion is upset and flatulence is frequent, the bowels are fickle in their action, and the indican and ethereal sulphates in the urine are markedly increased—sure signs of putrefactive changes in the bowel.

Intestinal Disinfection

In this class of cases intestinal disinfection is one of the principal lines of treatment to be adopted, and for this purpose nothing surpasses the use of Kerol Capsules

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Kerol Capsules

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

VERONIGEN

A liquid preparation of the Hypnotic Barbitone or Diethyl-barbituric acid has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, nor is cumulative in action, and in ordinary cases of insomnia, one fluid drachm of VERONIGEN is sufficient dose for an adult. As a preventive of post-operative vomiting, one to two fluid drachms of VERONIGEN may be given one and a half to two hours before general anæsthesia is produced, and as a result much less of the anæsthetic is required. As BARBITONE has a slight diuretic action, the mixture can be used when the heart is weak. Where sleeplessness is a consequence of pain, rest and relief can frequently be obtained by the administration of one dr[illegible] of VERONIGEN [illegible] two drachms of ELIXIR ACID. ACETO-SALICYLIC [illegible].

DOSE FOR ADULTS.—One fluid drachm diluted, one hour before going to bed.
For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN. Price 10/6 per lb. In 5, 10, 22, 40, and 90 oz. Bottles.

Introduced and Prepared only by C. J. HEWLETT & SON, LTD. Wholesale and Export Druggists
35-42, CHARLOTTE STREET, & 83-85, CURTAIN ROAD, LONDON, E.C.2.

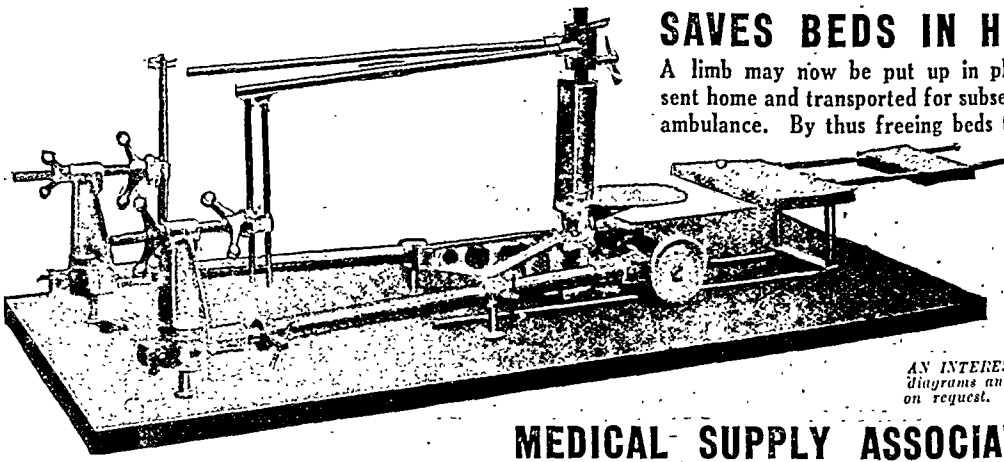
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

DEAF DOCTORS

AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: "*'Ardente' is a godsend to me*"; without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many doctors who are deaf use "ARDENTE."

"ARDENTE" is entirely different and uncopyable and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, tried, adjusted, supplied, and serviced.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation.

DOCTOR'S CHINA TEA

WHY IT IS PRESCRIBED FOR GASTRIC PATIENTS.

When ordinary tea is out of the question it is essential that only really good China should be drunk. The Doctor's China Tea has won the enthusiastic approval of practitioners simply because it is a perfect blend of a good China leaf with all excess tannin eliminated. It can therefore be prescribed for invalids and dyspeptics with safety—it has no ill after-effects.

STANIFORM

Regd. BRAND. Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is counter-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A amacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I have treated with 'Staniform' a very bad scald of chest in a child, who had boiling water spilt over her. It healed completely in fourteen days without a scar."

"I have tried 'Staniform' in the Out-patients' Department and both Nursing Staff and myself were amazed at results obtained. Long-standing, non-healing skin wounds healed after few applications."

"This is to certify that 'Staniform' has been used with great success in the Emma-Kliniek (Utrecht, Holland), in cases of bed-sores, in burns of heat and X-rays."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

Vapo-Cresolene

Sold by all Chemists

Write for descriptive Booklet No. 29.

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given hypodermically, and its action is short lived. Vapo-Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.

This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients, of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital, or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, golf courses, and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, football and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

TYKEFORD ABBEY, NEWPORT PAGNELL,
BUCKS.

FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.
Tel.: 64117.

For terms, etc., apply to the Medical Superintendent.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.

Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

RUTHIN CASTLE

(FORMERLY DUFF HOUSE, BANFF)

NEURALGIA AND NEURITIS

Few diseases cause so much suffering as nerve pains, such as sciatica, trigeminal neuralgia, brachialgia, and intercostal neuralgia.

This group of diseases is rapidly and effectively treated at Pistany (Czechoslovakia) by volcanic mud—driven to the surface by hot sulphur springs. Statistics show that of 100 patients, only less than 5% do not respond to the treatment—30% are completely relieved and 65% are considerably improved.

Pistany RADIO-ACTIVE Mud Packs and Compresses are simply and easily applied. This treatment may be successfully combined with other physiotherapeutic methods.

Applications, with copies of three testimonials, to be sent to the undersigned, Quay Street, Manchester, on or before Wednesday, April 22nd.

JOHN NALL, Secretary.

Glamorgan County Council.

PUBLIC ASSISTANCE COMMITTEE.

LLWYNYPIA HOSPITAL.

The Public Assistance Committee invite applications for the post of ASSISTANT MEDICAL OFFICER at the Llwynypia Hospital (182 beds), at a salary of £350, rising by annual increments of £25 to £450 per annum, together with residential emoluments valued for the purposes of the Local Government and Other Officers Superannuation Act, 1922, at £75 per annum. Accommodation is provided for an unmarried officer.

The post is established under the County Superannuation Scheme, and for this purpose a deduction of 5 per cent. of the annual salary will be made, repayable with interest on retirement before the pensionable age.

The person appointed will be required to give his whole time to the duties, under the control and supervision of the Medical Superintendent.

The appointment will be terminable by two months' notice on either side.

Applicants should have already held a resident hospital appointment, and should have had experience in a maternity department. Preference will be given to those who have had special experience in Orthopaedics and the administration of Anaesthetics. Applicants must not be over 35 years of age.

Applications for the appointment, stating age and qualifications, and accompanied by copies of not more than three recent testimonials, should be sent to the County Medical Officer, Glamorgan County Hall, Cardiff, and should be received by him not later than the first post on the morning of May 2nd.

Canvassing, personal or otherwise, will be a disqualification.

Glamorgan County Hall, Cardiff.

Borough of Cambridge.

Applications are invited from fully qualified Medical Practitioners under 35 years of age for the post of Whole-time ASSISTANT SCHOOL MEDICAL OFFICER and ASSISTANT MEDICAL OFFICER OF HEALTH. Salary £500 per annum, advancing by annual increments of £25 to £700; previous experience in a similar capacity will be taken into account in assessing the commencing salary.

Applicants must have had at least three years' practice since qualification, and must have had experience in the correction of errors of refraction. A Diploma in Public Health will be an additional qualification.

The successful applicant will be required to undergo a medical examination, and to contribute to the Local Government and Other Officers Superannuation Scheme.

A list of duties and application forms may be obtained (on receipt of a stamped addressed foolscap envelope) from the Secretary for Education, The Guildhall, Cambridge, to whom applications, with copies of not more than three recent testimonials, must be sent not later than Thursday, April 23rd.

The Guildhall, Cambridge. C. H. KEMP, Town Clerk.

April, 1931.

County Borough of Darlington.

HEALTH VISITOR.

Applications are invited from properly qualified persons for the appointment of Health Visitor.

The duties are chiefly concerned with Maternity and Child Welfare, and the successful applicant will be required to carry out such duties under the direction of the Medical Officer of Health.

The salary (under the Corporation's Scale), as at present adjusted by reference to the rise or fall in the cost of living, is £165 12s. per annum, and is subject to such other conditions of the Scale as are applicable. Additional allowances amounting to £11 per annum in respect of travelling and uniform are made.

The appointment will be subject to the Local Government and Other Officers Superannuation Act, 1922, and the successful applicant will be required to pass a medical examination.

Applications, stating age, qualifications, and experience, must reach the Medical Officer of Health, Feethams, Darlington, not later than Monday, April 20th.

Town Clerk's Office, Darlington. H. HOPKINS, Town Clerk.

April 4th, 1931.

Durham County Hospital (75 Beds.)

HOUSE SURGEON required immediately (two kept). Salary £150 per annum, with board and lodging.

Applications, with copies only of testimonials, stating age and when at liberty, to be sent to WM. R. WILSON, Secretary, 79, Saddler Street, Durham.

A Vacancy at present exists for an ASSISTANT MEDICAL SUPERINTENDENT in the MENTAL HOSPITAL, SINGAPORE, STRAITS SETTLEMENTS. Applicants, who must be British subjects of European parentage and under 35 years of age, should have had two years' experience as an Assistant Medical Officer at an Asylum or other Institution for Mental Diseases. Salary $500 per mensem (£700 per annum), rising by annual increments of $25 per mensem (£35 per annum) to $800 per mensem (£1,120 per annum) together with a temporary allowance of 10 per cent. if married, which may however be withdrawn at any time. Free quarters and free passage are provided. The appointment for three years in the first instance. Further particulars and forms of application may be obtained, on application in writing, from the Director of Recruitment (Colonial Service), Colonial Office, 2, Richmond Terrace, London, S.W.1.

Staffordshire County Council.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from Medical Practitioners holding the Diploma of Public Health for the above post. Candidates should have had at least three years' experience in the practice of their profession subsequent to qualification. Preference will be given to those who have held residential Hospital appointments.

The person appointed will work under the direction of the County Medical Officer, and the duties of the office will include School Medical and Maternity and Child Welfare work, in addition to such general public health work as may from time to time be prescribed.

The salary will be at the rate of £600 per annum, rising to £800 per annum by annual increments of £50, subject to a deduction of 5 per cent established under the Local Government and Other Officers Superannuation Act, 1922. Travelling expenses will be paid by the Council.

The appointment will be subject to three months' notice on either side.

Forms of application may be obtained from the undersigned, and should be returned by April 22nd, together with copies of not more than three testimonials.

County Buildings, EUSTACE JOY, Stafford. Clerk of the County Council.

March, 1931.

Borough of Ealing.

APPOINTMENT OF ASSISTANT TUBERCULOSIS OFFICER.

The Corporation invite applications from Medical Practitioners (male), of not more than 40 years of age, for the appointment of Assistant Tuberculosis Officer, at a commencing salary of £600 per annum, rising by annual increments of £25 to a maximum of £700. Applicants should have held, prior to April 1st, 1930, an appointment as Tuberculosis Officer, with the approval of the Minister of Health, or should, subsequent to qualification:

(1) Have had at least three years' experience in the practice of their profession;
(2) Have spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a hospital as resident officer in charge of beds occupied by general medical or surgical cases; and
(3) Have received special training, for a period of not less than six months, in the diagnosis and treatment of tuberculosis.

The candidate appointed will work under the administrative supervision of the Medical Officer of Health, and will be immediately responsible to the Senior Tuberculosis Officer.

This appointment is a designated post under the Local Government and Other Officers Superannuation Act, 1922.

Application forms may be obtained from the undersigned, to whom they should be returned not later than April 22nd.

Guildhall, W. M. FRAZER,
Hull. Medical Officer of Health.
April, 1931.

Brentry Colony.

APPOINTMENT OF RESIDENT MEDICAL SUPERINTENDENT.

The Board of Management of the Brentry Colony for Male Mental Defectives, situate at Westbury-on-Trym, near Bristol, invite applications from registered Medical Practitioners having had special training and experience in the Treatment of Mental Disorders for the post of Resident Medical Superintendent of their Institution containing 324 beds. The salary is £650 per annum, rising to £750 per annum, with quarters, rations (or allowance in lieu thereof), washing, light, and coal.

Further particulars and form of application may be obtained from the undersigned.

EDMUND R. ABBOTT, Hon. Sec.
Brentry Colony, 13, Victoria Street, Westminster, S.W.1.

County Council of the County of STIRLING.

ASSISTANT TO THE COUNTY MEDICAL OFFICER.

Applications are invited for the appointment of an Assistant to the County Medical Officer, at a commencing salary of £500 per annum, rising by annual increments of £25 to £700, and actual travelling expenses.

Applicants must be duly qualified, and must hold the Diploma in Public Health or similar qualification, and have had some experience of Eye work. Canvassing prohibited.

Forms of application may be obtained from the undersigned, with whom applications (with copies of three recent testimonials) must be lodged not later than April 20th.

JAMES LEARMONTH,
County Clerk.
County Buildings, Stirling. April 2nd, 1931.

Premium 1½ years' purchase.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

Who is your Patient?

A MAN or woman? Adult or child? A very necessary question when you prescribe a remedy for constipation—unless it is Agarol Brand Compound the original mineral oil and agar-agar emulsion with phenolphthalein. Then you need to give thought only to the dose. And that is simple. Begin with a tablespoonful for adults and a teaspoonful for children, at bedtime. Reduce the dose as improvement takes place.

No excess of mineral oil to make adjustments of the dose necessary. An emulsion as fine as it can be made, that mixes thoroughly with the intestinal contents, carries unabsorbable moisture to them and makes evacuation easy and painless.

Besides, it *gently stimulates* peristalsis, and thereby makes the result certain and the re-education of the bowel function possible.

One tablespoonful at bedtime —is the adult dose

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

THE PRACTITIONER

THE first four numbers of THE PRACTITIONER for 1931 have more than maintained the high reputation of the journal. The first, a greatly enlarged Special Number on Common Ailments, has had a record success and is completely sold out; the other three numbers contain valuable symposia on venereal disease, kidney disease and mental disease respectively, as well as other articles and practical notes on a great variety of medical subjects.

In the April issue Lord Moynihan, in a vigorous article, discusses the Milk Problem, while the May number will contain a symposium on rectal disease, with articles by Sir Charles Gordon-Watson, Mr. Lockhart-Mummery and Mr. Ernest Miles.

In July a Special Number will be published, devoted to Fractures and Accidents, a subject which is nowadays of the greatest importance to every general practitioner, as well as being a constant source of anxiety to him.

The annual subscription to "The Practitioner" is £2 2s., post free, to any part of the world, and includes two Special Numbers each year.

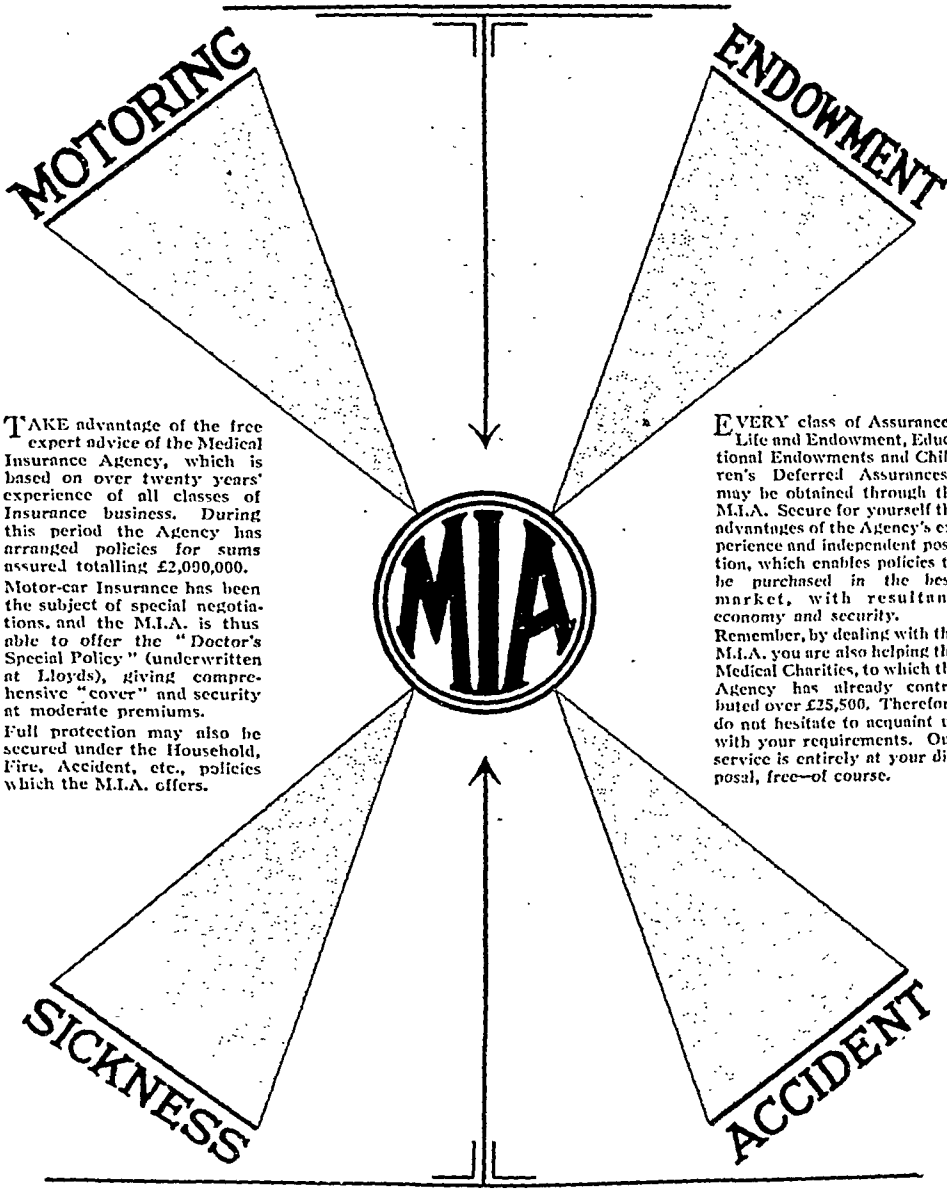
Insurance



TAKE advantage of the free expert advice of the Medical Insurance Agency, which is based on over twenty years' experience of all classes of Insurance business. During this period the Agency has arranged policies for sums assured totalling £2,000,000.

Motor-car Insurance has been the subject of special negotiations, and the M.I.A. is thus able to offer the "Doctor's Special Policy" (underwritten at Lloyds), giving comprehensive "cover" and security at moderate premiums.

Full protection may also be secured under the Household, Fire, Accident, etc., policies which the M.I.A. offers.

EVERY class of Assurance—Life and Endowment, Educational Endowments and Children's Deferred Assurances—may be obtained through the M.I.A. Secure for yourself the advantages of the Agency's experience and independent position, which enables policies to be purchased in the best market, with resultant economy and security.

Remember, by dealing with the M.I.A. you are also helping the Medical Charities, to which the Agency has already contributed over £25,500. Therefore do not hesitate to acquaint us with your requirements. Our service is entirely at your disposal, free—of course.

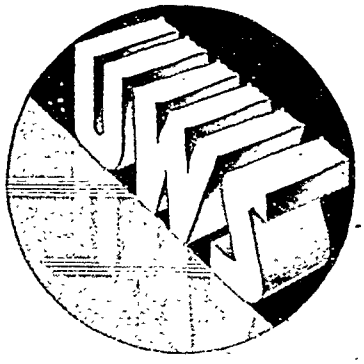
THE MOST SATISFACTORY METHOD OF ENSURING A SOFT WATER SUPPLY



It is a fact of considerable significance that 'Permutit' Water Softening Plants are to-day to be found in over 15,000 homes, and in the leading hospitals, clubs and hotels. No chemicals are used in the 'Permutit' System. This plant provides a soft water which is healthful and palatable to drink, at a moderate initial outlay and an infinitesimal running cost. The plant can be fitted without any alteration to existing arrangements.

Special Booklet Sent Free on Request
"Soft Water in the Home," an illustrated sixty-four page booklet, will gladly be sent to any doctor upon request.

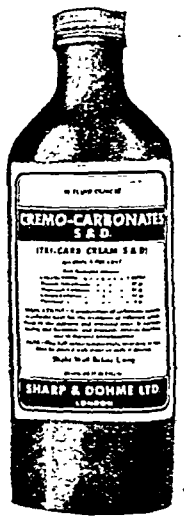
CREMO-CARBONATES

is pre-eminent as an Antacid and Corrective *because* . . . .



the submicroscopic size of the particles in colloidal suspension gives a greatly increased surface area and surface energy, and therefore greater acid-neutralizing ability.

Including two recognized antacids in colloidal form—magnesium and calcium carbonates, together with the protective bismuth subcarbonate—it is particularly effective in the treatment of gastric and duodenal ulcers, and in all digestive disorders caused by or accompanied by high gastric acidity.

Other Advantages

Entirely harmless in large doses, does not constipate, is not absorbed and therefore does not disturb the acid-base balance of the blood.

Supplied in 12 oz. bottles.

SHARP & DOHME, LTD.

OVALTINE

WHEN SLEEP IS DIFFICULT

Judged by the numerous reports received from physicians and also from grateful patients, the use of "Ovaltine" for ensuring sound refreshing sleep deserves the widest recommendation.

It has been remarked that a more helpful prescription could not be wished for because:

1. Taken last thing at night before retiring it exercises a pronounced sedative effect and one that is natural in every sense.
2. It has a pleasantly soothing action on the stomach and nervous system, and does not cause the slightest digestive unrest, or occasion constipation.
3. It promotes a sufficiency of healthful sleep without resourse to hypnotic drugs.

"Ovaltine" is a delicious concentrated extraction of malt, milk, and eggs, in the form of golden granules, which dissolve instantly in milk.

A liberal supply for clinical trial sent free on request.

The Pre-eminent Vitamin Food.

'BYNOTONE'

Contains essentially—bone marrow, yeast extract, hæmoglobin, liver fat and a proportion of irradiated ergosterol.

It is thus a concentrated nutrient, rich in the vitamins A, B and D and other elements which, often deficient in the ordinary everyday diet, are of vital importance to nutrition.

"Bynotone" is the ideal accessory food during the ages of active growth and adolescence, the periods of expectant and nursing motherhood and the stage of convalescence after acute disease.

Literature and clinical trial sample will be sent post free on request.

5% of pure iron (Fe)
in readily assimilable form

. . . does not constipate, disturb digestion or discolour teeth

Colloidal Iron Concentrate	83%
Pure Alcohol	6%
Sugar	10%
Flavouring	1%

That is the formula of this tonic preparation, which contains a larger percentage of assimilable iron than has hitherto been provided in either a general or colloidal form. A more rapid response may therefore be anticipated from the administration of this preparation, which is very pleasant to take and well tolerated by all patients.
Idozan has no constipating effect, it does not derange the stomach or discolour the teeth. Though incompatible with alkaline salts, it may be combined with Liq. Arsenicalis and vegetable tinctures. It is therefore very suitable for therapeutic administration, where it is desired to give large doses of iron; both as a restorative after illness and in cases of anæmia it can be prescribed either with or without additional drugs with confidence and freedom.

IDOZAN

IDOZAN HAS BEEN REGULARLY PRESCRIBED BY DOCTORS IN FIFTEEN DIFFERENT COUNTRIES

Samples and literature sent post free on request to Sole Distributing Agents:

MARSHALL'S Lysol is made to the original Lysol formula and specification. Every bottle is tested for purity and strength. Only the finest grade chemicals are used. Sample will be sent upon request to members of the medical and nursing professions. Lysol Ltd., Dept. K.14, Raynes Park, London, S.W.1.

NURSES, DOCTORS HOSPITALS, CLINICS
use *MARSHALL'S LYSOL*

The preference shown to MARSHALL'S Lysol by the medical profession is not an accidental one. It is not merely a matter of old-established custom . . . It is a matter of experience and knowledge: of reliance placed on an antiseptic that has never betrayed a trust. MARSHALL'S Lysol is SAFE. It is a germicide and antiseptic of *proven* worth . . . harmless to tissue when used in the correct dilution.

SAFE

CONTRAMINE

Contramine is a typical example of a chemotherapeutic drug which, according to the present prevailing medical opinion, acts by building up the resistance of the patient and not by the direct destruction of the organism. Of these chemotherapeutic drugs, those with complex molecules with a sulphur atom loosely attached to the molecule possess remarkable power to build up the patient's resistance against many chronic infections.

Contramine is such a sulphur compound with a complex molecule, and it is probably unequalled by any other drug in its action in building up resistance against such infections as the chronic complications of gonorrhoea.

THE BRITISH DRUG HOUSES LTD. LONDON N-1

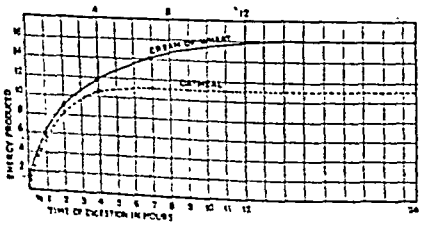
Co118

Research Institute investigates the relative value of wheat cereal and oats as first solid diet

Greater digestibility and 50% more energy intake proved for wheat

Recent tests by a leading biochemical institute have established the superiority of "Cream of Wheat" over oatmeal as a first starch food for infants. Some of the advantages are indicated in the accompanying graphs, which summarize the results of careful experimental work on these two cereals.

DIASTATIC DIGESTION

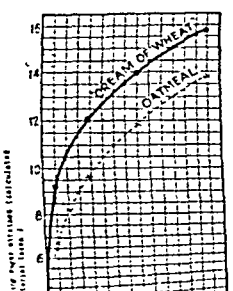


Not only did the digestion of "Cream of Wheat" continue at a scarcely diminished rate 4 hours after the digestion of oatmeal was practically at a standstill, but the amount of sugar yielded was 50% greater. "Cream of Wheat" thus affords 1½ times as much energy as oatmeal, and, by maintaining the blood sugar at an optimal level, helps to bring about the complete hydrolysis and metabolization of fats.

PANCREATIC DIGESTION

The growing tendency among practitioners to give starch as early as the third month makes these tests of paramount importance. Many leading paediatrists are putting "Cream of Wheat" on their diet sheets for infants.

It can be given both as a first solid diet—particularly for children prone to indigestion or fat intolerance—and as an adult food in the post-operative period. A sample and fuller details of the above tests will be gladly sent you on receipt of a professional card. —Dept. W.3, Fassett & Johnson, Ltd., 86, Clerkenwell Road, London, E.C.1.



Stomach Tissue

in the treatment of

Pernicious Anæmia

'Byno Eugastrol'

A combination of hog's stomach tissue extract with 'Bynin' Liquid Malt.

The usually recommended daily dose is three tablespoonfuls, which represents an amount of extract equivalent to 100 grammes of fresh stomach tissue.

A very palatable preparation.

In bottles, 4 oz., 10 oz. and 20 oz.

'Kapsol Eugastrol'

Presents hog's stomach tissue extract in the form of capsules, each equivalent to 25 grammes of fresh stomach tissue.

The usual daily dose is four capsules.

In tins containing 20, 40 and 80 capsules.

INDISPENSABLE!

WHEN EXHAUSTION PROHIBITS SOLID FOOD . . .

WHEN ANOREXIA RETARDS RECOVERY . . .

In serious illness when vitality is at its lowest and solid foods are prohibitive, these essences are of inestimable value.

Combining quick stimulation with almost effortless assimilation Brand's Essences of Beef or Chicken revive vitality while conserving the patient's energy.

99 out of every 100 doctors recently interviewed recommend them in illness and convalescence.

Suave and non-irritating, Brand's Essences can be digested 40 minutes quicker than ordinary foods and without the formation of residue.

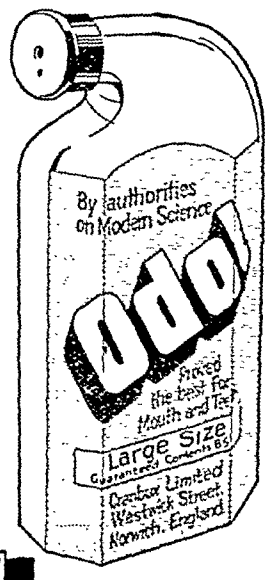
They are prepared by an exclusive process from the finest freshly killed English meats. No preservatives or colouring matter are used. They are easy to swallow and deliciously appetizing.

Samples will be gladly sent on receipt of a professional card. Dept. F31, Brand & Co., Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

BRAND'S ESSENCES OF BEEF OR CHICKEN

BY APPOINTMENT

What three doctors say about Odol



1. STOMATITIS

"I have often recommended Odol to patients suffering from Stomatitis and have found it very efficacious."
. . . . . M.R.C.S.Eng., L.R.C.P.Lond.

2. NOSE WORK

"I use a solution of Odol for all nose work, washing out the antrum and sinuses, etc. It is excellent and a soothing antiseptic." . . . . . M.D.

3. ZYMOTIC DISEASES

"It is most excellent in septic conditions of the mouth such as one finds in the zymotic diseases."
. . . . . M.C., L.R.C.P., M.D.H.

Not only is Odol definitely antiseptic—not only does it destroy disease germs of the mouth and throat—not only does it check the growth of bacteria for hours after use—but it is perfectly safe. Non-toxic, non-caustic and non-acid, Odol does not injure the teeth or the mucous membrane of the mouth.

Samples and literature will gladly be sent to any member of the Medical Profession on application to:—

MALNUTRITION and MARASMUS

Mellin's Food has met with very remarkable success in the treatment of infants of retarded development due to nutritional disorders. Infants in this condition need a food substance that is assimilated quickly and one that may be taken in comparatively large amounts.

The carbohydrate maltose, which is the principal sugar in Mellin's Food, is a food substance that offers the greatest assistance in the adjustment of the diet because it yields immediately available nutrition and can be at once utilised to furnish the necessary heat and energy.

Mellin's Food

"MODIFIED MILK IN INFANT FEEDING"

The above-named booklet of 64 pages, which gives further information regarding the use of Mellin's Food in cases of malnutrition, will be gladly sent to Members of the Medical Profession.

MELLIN'S FOOD LTD., LONDON, S.E.15.

'PANOPEPTON'

Ideal Food for the Sick.

Agreeable, highly Diffusible, Assimilable.

The patient or the nurse may stretch out a hand at any time, in the night or any daylight hour, and find in 'Panopepton' a stimulating, fortifying food, especially "heartening." It quickly and substantially relieves that "gone feeling" consequent upon innutrition.

'Panopepton' is a dynamic food, the naturally soluble and hydrolysible substance of the entire beef and the entire wheat, set free by direct physiological conversion by contact with actual gland tissue juice of the stomach and pancreas.

'Panopepton' presents this important complex of nitrogenous derivatives, associated mineral and organic extractives, as well as those of the glands by which this physiological conversion is accomplished.

'Panopepton' is a food in imitation of nature at its best, and for this reason is of special service in the nutrition of the sick.

The rich colour, the agreeable, diffusible, realizable properties of 'Panopepton' are peculiar to itself.

Panopepton' should be taken without dilution—cold if convenient.

Medisoap

MIDGLEY'S MEDICATED SOAP

The word MEDISOAP is a registered trade-mark indicating the pure soap base made and scientifically medicated by CHARLES MIDGLEY, LTD., according to published formulae. This method of skin medication has been brought into favour by the ease with which applications can be made and the certainty of absorption through regularity of use by the patient.

A PRESCRIBER'S INDEX

relative to the comprehensive range of Medisoaps is available to members of the medical profession on application to EVANS' BIOLOGICAL INSTITUTE, RUNCORN.

Medisoap Depots all over the country.

Sole Makers:

SEBORRHOEA

In the treatment of scalp conditions Medisoap Therapy merits special consideration, as the presence of hair complicates other schemes of treatment. The following containing Resorcin are very effective:—

MEDISOAP No. 40, containing Resorcin 11% and Acid Salicylic 11%.

MEDISOAP No. 41, containing Resorcin 11%, Acid Salicylic 12% and Sulphur 10%.

MEDISOAP No. 57, containing Resorcin 21%.

MEDISOAP No. 71, containing Resorcin 11% and Sulphur 11%.

For further particulars see *"Prescriber's Index."*

RADIO-MALT

Vitamins A B_1 B_2 and D

In Convalescence

After serious illness when resistance is reduced and the patient lacks vitality and recuperative power, the value of a vitamin tonic of the nature of Radio-Malt is incalculable.

Each of the Vitamins A B_1 B_2 and D contained in Radio-Malt performs a specific function, with the result that the resistance of the patient is built up and the depleted reserves are replenished.

Peptonised Beef Jelly (BENGER)

and

Peptonised Chicken Jelly (BENGER)

These can be served either in their jelly state with a few biscuits, or dissolved in hot water in "beef-tea" form, making a valuable restorative readily assimilated by weak digestions.

Containing much of the flesh-forming elements of the meat in soluble form, these peptonised preparations are superior in effect to ordinary essences or extracts. Added to soups they considerably increase the nutrient value.

In hermetically sealed glass jars, 2/- and 3/- each.

NOTE.—Benger's Peptonised Beef Jelly and Chicken Jelly are entirely free from preservatives.

BENGER'S FOOD, LTD., Otter Works, MANCHESTER.

BENGER'S Food

BETTER MILK FOR BABIES

FACTS ABOUT
LACTOGEN

Vitamins and Minerals

To fulfil the requirements of the rapidly growing child an adequate supply of vitamins and mineral salts must be provided.

Milk furnishes a sufficiency of these essentials, and in Lactogen their complete conservation is effected.

For the final desiccation of the modified fresh milk the roller process is employed. The heat applied is thus reduced to a minimum and the exposure confined to a matter of seconds.

Lactogen provides a full complement of mineral salts in organic combination, together with the adequate vitamin allowance. It is a complete and balanced diet furnishing the infant with every essential necessary for good health and normal development.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

"LACTOGEN"
REG. TRADE MARK
BETTER MILK FOR BABIES

(Aesculapius)

THE ANAEMIAS

PERNICIOUS ANAEMIA

Careful observations of large numbers of cases and the numerous notable reports received during the last four years justify the assertion that if treatment with HEPATEX is properly carried out, marked benefit results in most cases within a few days. Should the improvement not occur within three weeks it is probable that it is not a case of Pernicious Anaemia, or there may be some factor intimately connected with the gastric aspects of the condition which does not respond to Liver Therapy. For such cases attention has recently been turned to the haematopoietic value of stomach tissue with promising results, and in this connection we have produced GASTREXO, a scientifically prepared desiccated and defatted whole stomach substance.

SECONDARY ANAEMIA

For the treatment of the Severe Secondary Anaemias the use of Hepatex may be of inconstant value, but combined with iron it has proved to be eminently satisfactory. For cases of stubborn Secondary Anaemia where powerful stimulation of the blood regenerating organs is highly desirable HEPATEX WITH IRON is strongly recommended. The special form of iron used is greatly superior to ordinary iron preparations as regards assimilation and produces no disagreeable after-effects.

HEPATEX — Issued in 4 oz. bottles. 1 fluid drachm equals 2 oz. of fresh liver.

HEPATEX with IRON — Issued in 2 oz. bottles, contains 1 grain of metallic iron in 1 drachm.

GASTREXO — Issued in boxes of 12 × 10 grammes and tins of 240 grammes. 10 grammes is equivalent to 80 grammes of whole substance.

The Superiority of Cod Liver Oil as a Cure for Rickets

Leading Authorities have proved by the most painstaking researches that:

A certain number of D-vitamin units in the form of Cod Liver Oil is far more effective in the treatment of human Rickets than the same or even double the number of these units in the form of irradiated Ergosterol.

Read what Professor E. Poulsson says on the subject in his recent paper "On the Action of Cod Liver Oil and Irradiated Preparations in Rickets", published by the State Vitamin Institute in Oslo.

This paper may be obtained free by post on application to the State Vitamin Institute.

The world-renowned Norwegian Cod Liver Oil has always been noted for its high quality. Exported under control of the Norwegian State.

THE ALEMANNI AND THE BURGUNDIANS.—The Alemanni, *i.e.*, the "All men," dwelt at first in the basin of the Main and were often at war with the Romans. About A.D. 400 they crossed the Rhine, conquered Alsace and part of Switzerland round Lake Constance, settled there and built up a kingdom which lasted until A.D. 495, when it was absorbed in the Frankish empire of Clovis. Their name survives as "Allemagne" and their dialects, Alemannic and Suabian, which remained Teutonic, are now spoken in Württemberg, in part of Bavaria, in German Switzerland, and in the south of Baden and Alsace. The Burgundians were in constant warfare with the Alemanni and were friendly to the Romans; they, unlike the Alemanni, allowed their speech to become modified into a Romance tongue. They first established a kingdom in the fifth century A.D., and extended its boundaries until it included among its chief towns Vienne, Lyons, Besançon, Geneva, Autun and Macon. The occupation by the Burgundians of the district round Worms is of interest, for this was the scene of the destruction of the Burgundian heroes by the Huns, described in the *Nibelungenlied*. Both tribes developed industrial art. An example of Burgundian metal work is illustrated.

Remarks ON CONSERVATIVE GYNAECOLOGICAL SURGERY *

BY

W. BLAIR BELL, B.S., M.D., F.R.C.S.

HON. F.A.C.S.

PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, UNIVERSITY OF LIVERPOOL; OBSTETRICAL AND GYNAECOLOGICAL SURGEON, ROYAL INFIRMARY, LIVERPOOL; PRESIDENT, BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

Some day perhaps a surgeon, possessing a wide historical knowledge of the art and science of surgical intervention, and gifted with a philosophical quality of mind, will tell us why the rugged efforts of the earliest times have lingered on, even to the present day, side by side with the advance of scientific methods in gynaecological surgery. I cannot do more here than indicate the circumstances as they appear to me.

Until a hundred years ago surgery was almost entirely urgent in character—the surgery of injuries of war or of peace time. Gradually physiological and pathological knowledge was acquired, and this stimulated further surgical endeavour, at first without corresponding reward. Then came anaesthesia and antiseptic surgery, which made operations of convenience as well as life-saving and health-giving procedures possible.

The gynaecological enterprises of the general surgeon, following on the work of men like Spencer Wells and Lawson Tait, soon commenced: "Surely if *they* can remove ovaries, tubes, and uteri, so can we," said the general surgeon, and acted accordingly. For a time gynaecological surgery became an eradicative competition among all those who handled the knife; and, as I have indicated, to some extent it still is. At the end of last century, however, Liverpool began to tower over the rest of the surgical world in regard to conservative surgery. A scientifically-minded general surgeon, William Alexander, who will in due time be posthumously accorded his rightful place as a wise pioneer, as has happened in the case of Hugh Owen Thomas of the same city, was making contributions to conservative gynaecological procedures of the highest value. Elsewhere gynaecological surgery, Alexander neglected, lagged behind. The general surgeon still removed everything he found abnormal in the pelvis, and the gynaecologist did the same, when, indeed, he was not prevented from operating altogether by his surgical colleagues, as obtained at St. Bartholomew's and other hospitals in London.

About thirty years ago, when gynaecology shook off the medical trammels imposed upon it in many places by its surgical brethren, and reached out for surgical recognition, it was found that the physiologists, anatomists, and pathologists had overlooked the fact that before a person can function normally or abnormally he must be born, that the organs concerned in this process are worthy of consideration, and that all that is gynaecological is not restricted to the pelvis, as is still believed by the ignorant to-day. Consequently it was necessary that the gynaecologist should investigate the structure of the female genitalia and the physiological performances of which these organs are capable. This was the state of affairs when I myself entered the field of gynaecology: very little was known of the physiology and pathology of the genital organs and their functions. Only in the last few years has any real help been given by others who are not practising gynaecologists; so the fact remains that the gynaecologists of the present generation have themselves laid down the scientific lines on which recent advances and refinements have proceeded, and in so doing have legitimately excluded the conscientious general surgeon from cobbling on lasts with which he is not familiar.

It is therefore of the utmost importance that those practising gynaecology should have one mind on the question of conservative surgical procedures. This is physiological surgery, as opposed to the older anatomical surgery. Yet I have myself in recent years taken part in many controversies concerning the value ("if any," some have said) of the ovary in the functional equipment of woman, and the advantages of operations designed to conserve as far as may be her feminine state and functions, as opposed to what has been called the "clean sweep."

It seems curious that controversy should ever arise on such matters, for the principle of all surgical operations, whatever region be concerned, is the same: the mechanical treatment of lesions causing symptoms with the conservation of structure and function, so long as this practice does not endanger the life of the patient. I am, however, happy to think that, although the last discussion on this subject took place as recently as 1927,[12 18 22] it would be difficult to-day to find an advocate of the "clean sweep" as a routine procedure. It has never seemed to me unreasonable to regard the conservation of the ovarian function as of no less biological importance than that of the testicular. The fictitious difference some have sought to maintain has in reality been created by the prominent position of the male organ, and the pride men take in their potency! Yet the possibility of conception, pregnancy, and parturition is no less important psychically and physically to a woman, because she alone is capable of these life-giving phenomena.

FUNCTIONS OF THE PELVIC GENITALIA AND PASSAGES

Primarily reproductive, the genital organs in the consummation of this function are closely linked up with the metabolism of the soma. We cannot regard the reproductive phenomena as processes apart from the rest of the bodily functions.

Formerly the genitalia of woman were regarded as being local in function as well as in position. Now we know that from birth till after the menopause the genital secretions and functions play a very important part in determining the mental and physical development of the individual, and in maintaining the attributes of the normal woman. Moreover, as I showed many years ago, the ovaries are but one link in the chain of organs, such as the pituitary and thyroid, which form a genital system.[4] Ablation or serious disturbance of any one of these may seriously affect the other links in the chain, and therefore the metabolism of the body, with many physical and psychical consequences.

To-day, all surgeons have acquired a physiological, in place of a purely anatomical, outlook; so, with such knowledge as I have outlined, the scientific gynaecologist sets before him the ideal of preservation of function. Conservative gynaecological surgery, then, is concerned with the maintenance of the ovarian function and menstruation, and with the fostering of conception and childbirth.

CONSERVATIVE OPERATIONS ON THE OVARIES

Ovarian Resection.—One of the commonest and most important of conservative operations on the ovary is partial resection of the organ in well-defined circumstances. Unfortunately it is usually the custom of gynaecological surgeons to remove, quite unnecessarily, an ovary which is the seat of an innocent neoplasm. Often enough mere bisection of the specimen subsequently to removal shows us on naked-eye examination that part of the ovary could have been preserved, for very commonly—indeed, almost

* The substance of addresses, with lantern illustrations, delivered to the Southport Medical Society on March 4th, 1931, and to the Blackburn Medical Society on March 11th, 1931.
